The full veſſel is always to be left open at the top, but the mouth of the other muſt be cloſed with a cover of wood, in order the better to keep down and fix the ſpirit in the body of the liquor; otherwiſe, it might eaſily fly off in the heat of fermentation. The veſſel that is only half full ſeems to grow hot, rather than the other, becauſe it contains a much greater quantity of the vine-twigs and ſtalks, than that, in proportion to the liquor; above which the pile, riſing to a conſiderable height, conceives heat the more, and ſo conveys it to the wine below.

Vinegar is a medicine of excellent uſe in all kinds of inflammatory and putrid diſorders, either internal or external: in ardent bilious fevers, peſtilential and other malignant diſtempers, it is recommended by Boerhaave as one of the moſt certain ſudorifics. Weakneſs, fainting, vomiting, hyſterical and hypocondriacal complaints have alſo been frequently relieved by vinegar applied to the mouth or noſe, or received into the ſtomach. Diſtilled vinegar has the ſame virtues, only in a ſtronger degree.

There are alſo medicated vinegars, as vinegar of antimony, of elder, litharge, roſes, ſquills, treacle, &c. which derive their chief virtues from the vinegar.

VIPER, the name of a well known ſerpent, common in many parts of England.

The bathing the part bit by a viper with olive oil, is ſaid to effectually prevent the fatal conſequences, that would otherwiſe attend it.

VIVES, a diſeaſe in horſes, which differs from the ſtrangles only in this, that the ſwellings of the kernels under the ears of the horſe (which are the parts at firſt chiefly affected) ſeldom gather, or come to matter, but by degrees perſpire off, and diſperſe, by warm cloathing, anointing with the marſhmallow ointment, and a moderate bleeding or two. But ſhould the inflammation continue, notwithſtanding theſe means, a ſuppuration muſt be promoted by the methods recommended in the ſtrangles. *See the article* STRANGLES.

When theſe ſwellings appear in an old or full-aged horſe, they are ſigns of great malignity, and often of an inward decay, as well as forerunners of the glanders.

The mercurial ointment mentioned in the article STRANGLES may be prepared thus:

> Take of crude mercury, or quickſilver, one ounce; Venice-turpentine half an ounce; rub together in a mortar till the globules of the quickſilver are no longer viſible; then add two ounces of hogslard.

Some authors recommend this ointment to be uſed at firſt, in order to diſperſe the ſwellings, and prevent their coming to matter; bleeding and purging at the ſame time for that purpoſe; but as in young horſes they ſeem to be critical, the practice by ſuppuration is certainly more eligible and ſafe; for want of properly affecting which, the humours frequently ſettle, or are tranſlated to the lungs, and other bowels; or falling on the fleſhy parts of the hind quarters, form deep impoſtumes between the muſcles, which diſcharge ſuch large quantities of matter, as ſometimes kill the horſe, and very often endanger his life. *Bartlet's Farriery, page* 99.

ULCER, a ſolution of the ſoft part of an animal body, together with the ſkin.

The firſt intention in the cure of ulcers is bringing them to digeſt, or diſcharge a thick matter; which will in general be effected by the green ointment, or that with precipitate; but ſhould the ſore not digeſt kindly by theſe means, but diſcharge a gleety thin matter, and look pale, you muſt then have recourſe to warmer dreſſings, ſuch as balſam, or oil of turpentine, melted down with your common digeſtive, and the ſtrong beer poultice over them; it is proper alſo in theſe kind of ſores where the circulation is languid, and the natural heat abated, to warm the part, and quicken the motion of the blood, by fomenting it well at the time of dreſſing; which method will thicken the matter, and rouſe the native heat of the part, and then the former dreſſings may be re-applied.

If the lips of the ulcer grow hard or callous, they muſt be pared down with a knife, and afterwards rubbed with the cauſtic.

Where ſoft fungous fleſh begins to riſe, it ſhould carefully be ſuppreſſed in time, otherwiſe the cure will go on but ſlowly; if it has already ſprouted above the ſurface, pare it down with a knife, and rub the remainder with a bit of cauſtic; and to prevent its riſing again, ſprinkle the ſore with equal parts of burnt allum, and red precipitate; or waſh with the ſublimate water, and dreſs with dry lint even to the ſurface, and then rowl over a compreſs of linnen as tight as can be borne; for a proper degree of preſſure, with mild applications, will always oblige theſe ſpongy excreſſences to ſubſide, but without bandage the ſtrongeſt will not ſo well ſucceed.

All ſinuſſes, or cavities, ſhould be laid open as ſoon as diſcovered, after bandages have been ineffectually tried; but where the cavity penetrates deep into the muſcles, and a counter opening is impracticable or hazardous; where by a continuance, the integuments of the muſcles are conſtantly dripping and melting down; in theſe caſes injections may be uſed, and will frequently be attended with ſucceſs. A decoction of colcothar boiled in forge-water; or ſolution of lapis medicamentoſus in lime-water, with a fifth part of honey and tincture of myrrh, may be firſt tried, injecting three or four ounces twice a day, or ſome reſin melted down with oil of turpentine may be uſed for this purpoſe: if theſe ſhould not ſucceed, the following, which is of a ſharp and cauſtic nature, as recommended on Mr. Gibſon's experience.

> Take of Roman vitriol half an ounce, diſſolve in a pint of water, then decant and pour off gently into a large quart bottle; add half a pint of camphorated ſpirit of wine, the ſame quantity of the beſt vinegar, and two ounces of Ægyptiacum.

This mixture is alſo very ſucceſsfully applied to ulcerated greaſy heals, which it will both cleanſe and dry up.

Theſe ſinuſſes or cavities frequently degenerate into fiſtulæ, that is, grow pipey, having the inſide thickened, and

and lined as it were with a horny callous ſubſtance. In order to their cure, they muſt be laid open, and the hard ſubſtance all cut away; where this is impracticable, ſcarify them well, and truſt to the precipitate medicine made ſtrong, rubbing now and then with cauſtic, butter of antimony, or equal parts of quickſilver and aqua fortis.

When a rotten or foul bone is an attendant on an ulcer, the fleſh is generally looſe and flabby, the diſcharge oily, thin, and ſtinking, and the bone diſcovered to be carious, by its feeling rough to the probe paſſed through the fleſh for that purpoſe. In order to a cure, the bone muſt be laid bare, that the rotten part of it be removed; for which purpoſe, deſtroy the looſe fleſh, and dreſs with dry lint; or the doſſils may be preſſed out of tincture of myrrh or euphorbium: the throwing off the ſcale is generally a work of nature, which is effected in more or leſs time, and in proportion to the depth the bone is affected; tho' burning the foul bone is thought by ſome to haſten its ſeparation.

Where the cure does not properly ſucceed, mercurial phyſick ſhould be given, and repeated at proper intervals: and to correct and mend the blood and juices, the antimonial and alterative powders, with a decoction of guaiacum and lime-waters, are proper for that purpoſe. *Bartlet's Farriery, page* 253.

ULIGINOUS, an appellation given to a moiſt, mooriſh, and fenny ſoil.

OMBEL, the extremity of a ſtalk or branch of a plant, divided into ſeveral peduncles, or rays, beginning from the ſame point, and opening in ſuch a manner, as to form an inverted cone.

UMBELLIFEROUS *Plants*, thoſe whoſe flowers are produced in an umbel, on the top of the ſtalks, ſomewhat reſembling an umbrella. Of this kind are the fennel, parſley, parſnip, carrot, hemlock, &c.

UNDERWOOD, coppice, or any wood not accounted timber. *See the article* COPPICE.

VOOR, fallow land. *See the article* FALLOW.

URE, the udder of a cow, ſheep, &c.

URITH, etherings, or windings of hedges.

URRY, a ſort of blue or black clay, lying near a vein of coal.

URINE, a ſerous and ſaline matter ſeparated from he blood of animals, and emitted by the canal of the turethra.

It is of excellent uſe as a manure, when deprived of its hot fiery particles by time, which will ſo alter its nature as to render it an extraordinary fertilizer of every kind of ſoil. Columella certifies that old urine is excellent for the roots of trees. Mr. Hartlib commends the Dutch for preſerving the urine of cows as carefully as they do the dung, to enrich their lands; and inſtances a woman he knew near Canterbury, who ſaved in a pail all the urine ſhe could, and when the pail was full, ſprinkled it on her meadow, the graſs of which looked yellow at firſt, but afterwards grew ſurprizingly. Similar to this is what Mr. Bradley relates, as of his own knowledge. Human urine was thrown into a little pit conſtantly every day, for three or four years. Two years after, ſome earth was taken out of this pit, and mixed with twice as much other earth, to fill up a hollow place in a graſs walk. The turf which was laid upon this ſpot grew ſo largely and vigorouſly, beſides being much greener than the reſt, that, by the beſt computation he could make, its graſs, in a month's time, was above four times as much in quantity as that of any other ſpot of the ſame ſize, though the whole walk was laid on very rich ground. The author of the Engliſh Improver is therefore very right in ſaying, that human urine is of greater worth, and will fatten land more, than is generally imagined by our farmers, whom he adviſes, to take all opportunities of preſerving this, and every ſort of urine, for their ground, as carefully as is done in Holland.

USTILAGO, the ſame with burnt grain. *See the article* BURNT-GRAIN.

UTENSIL, a domeſtic moveable of any kind.

W.

WAL

WAD, black lead.

WAGGON, a vehicle or carriage, of which there are various forms, accommodated to the different uſes they are intended for. *See the article* WHEEL.

WAIF, an eſtray, which, for want of the owner's appearance after it has been cried and publiſhed in the neighbouring markets, is forfeited to the lord of the manor.

WALK, among horſemen, is the ſloweſt, and leaſt raiſed of all a horſe's goings. It is performed by a horſe's lifting up his two legs on a ſide, the one after the other, beginning with the hind leg firſt. Thus, if he leads with the legs of the right ſide, then the firſt foot he lifts is the far hind-foot, and in the time he is ſetting it down, (which in a ſtep is always ſhort of the tread of his fore-foot on the ſame ſide) he lifts his far fore-foot, and ſets it down before his near fore-foot. Again, juſt as he is ſetting down his far fore-foot, he lifts up his near fore-foot, and ſets it down again juſt ſhort of his near fore-foot; and juſt as he is ſetting it down, he lifts his near fore-foot, and ſets it down beyond his far fore-foot.

WALL, the principal part of a building, as ſerving both to incloſe it, and ſupport the roof, floors, &c.

Walls are diſtinguiſhed into various kinds, frem the matter whereof they conſiſt, as plaſtered or mud-walls, brick-walls, ſtone-walls, flint, or boulder walls, and boarded walls. In all which theſe general rules are to be regarded. 1. That the right angle therein depending is the true cauſe of all ſtability, both in artificial and natural poſition. 2. That the maſſieſt and heavieſt materials be the loweſt, as fitter to bear than to be bore. 3. That the walls, as they riſe, diminiſh proportionably in thickneſs, for eaſe both of weight and expence. 4. That certain courſes or ledges, of more ſtrength than the reſt, be interlaid, like bones, to ſtrengthen the whole fabrick.

Brick-walls are the moſt important and uſual amongſt us. In theſe, particular care is to be taken about laying of the bricks; that in ſummer they be laid as wet, and in winter as dry, as poſſible, to make them bind the better with the mortar: that in ſummer, as faſt as they are laid, they be covered up, to prevent the mortar, &c. from drying too faſt: that in winter they be covered well to protect them from rain, ſnow, and froſt, which are all enemies to mortar: that they be laid joint on joint in the middle of the walls as ſeldom as may be: but that good bond be made there as well as on the outſide. Care is to be taken that the angles be firmly bound, which are the nerves of the whole edifice. In order to which, in working up the walls of a building, it is not adviſable to raiſe any wall above eight feet high, before the next adjoining wall be brought up to it, that ſo good bond may be made in the progreſs of the work; it may be worth notice, that a wall a brick and a half thick, with the joint, will be in thickneſs fourteen inches, or very near; whereas one hundred and fifty or one hundred and ſixty bricks will lay a yard ſquare meaſured upon the face of the building; and to the ſquare of ten feet are uſually allowed ſeventeen hundred or eighteen hundred bricks. Flint, or boulder walls, are much uſed in ſome parts of Suſſex and Kent, for fence-walls, round courts, gardens, &c. A right and left-handed man ſits well for this work, as they have a hod of mortar poured down upon the work, which they part between them, each ſpreading it towards himſelf, and ſo they lay in the flints. The mortar for this work muſt be very ſtiff.

WALLNUT-TREE, the name of a well known tree, formerly held in great eſteem in this country, for its wood, which is, in fact, often very finely veined; but, on account of its aptneſs to be worm-eaten, it has of late given place to the beautiful and much ſounder mahogany, with which our cabinet-makers have been pretty plentifully ſupplied from the Britiſh ſettlements in the Weſt Indies.

As an uſeful fruit tree, independent of its timber, which is, however, ſtill of good value, it merits the huſbandman's attention; nor can the gentleman eaſily find a more ſtately one to adorn his park with, or to form a noble avenue to his manſion.

Theſe trees are raiſed from their nuts, which it is beſt to keep in dry ſand, with their outer covers on, till February; that being the right time for planting them. If they are intended for timber trees, they ſhould be ſown in the places where they are to remain, in order that the breaking or otherwiſe ſhortening of their roots, and eſpecially thoſe of the tap kind, may not ſtint their growth, and make them run out in branches: but if they are deſigned for fruit, their fertility will be increaſed by tranſplanting them, becauſe their downright roots, which are thoſe that chiefly encourage the luxuriant growth of wood in all ſorts of trees, will be thereby checked, and they will be made, in lieu of them, to ſtrike out numbers of lateral roots, which, as experience has proved, always conduce greatly to the production of the largeſt and faireſt fruit. The moſt proper ſeaſon for tranſplanting them is when their leaves begin to decay; and the beſt age, when they have had three or four years growth in the nurſery. Mr. Miller ſays he has frequently experi-

enced that there is little danger of their ſucceeding altho' they be eight or ten years old when they are tranſplanted: but, however that may be, it is certain that they will root beſt, grow largeſt, and laſt longeſt, if they are removed young. The leſs their branches are cut at the time of tranſplanting, or indeed at any time after, the better they will proſper; for much lopping often cauſes them to decay: but if there be a neceſſity for taking off any of their boughs, it ſhould be done early in September, that the wound may have time to heal before the cold and wet comes on. It is likewiſe eſſential to cut the branch off quite cloſe to the trunk, leſt the ſtump which is left ſhould decay, and rot the body of the tree; to prevent which, eſpecially if the wound be large, it will be right to ſmooth it well with a chiſſel, and then to cover it over carefully with a cement of clay or wax, as in the caſe of grafting, with a piece of tarpawling, or of ſheet lead, over that.

Theſe trees ſhould not be planted nearer together than forty feet, and more may yet be better, if they are deſigned for fruit. They delight in a firm, rich, loamy ſoil, or ſuch as is inclinable to chalk or marl; and they will thrive very well in ſtony ground, or on chalk hills, as is evident from thoſe large plantations near Leatherhead, Godſtone, and Carſhalton in Surry, where great numbers of theſe trees planted upon the downs produce annually large quantities of fruit, to the no ſmall advantage of their owners.

In order to preſerve this fruit, it ſhould be left upon the tree till it is thoroughly ripe, and then, as it would be exceedingly troubleſome to gather it by hand, it may be beaten off, but not with ſuch violence as is commonly uſed, from a miſtaken notion that the tree is improved thereby; for moſt certainly it cannot be benefited by that rough way of forcing off the young wood upon which this fruit grows. The nuts thus obtained ſhould be laid in heaps for two or three days, after which they ſhould be ſpread out, and when they have parted from their huſks, which they will then ſoon do, and have afterwards been well dried in the ſun, to remove the moiſture of their ſhells, which would otherwiſe make them mould, they ſhould be laid up in a dry place, where neither mice nor other vermin can get at them. In this manner they will remain good for four or five months: or, which is a yet better way, and will keep them ſtill longer, let them, when their outward moiſture has been dried by the ſun, be put up in jars, or other cloſe veſſels, with dry ſand between their interſtices. The laying of them for four or five hours in an oven gently heated, as is the practice of ſome, will indeed dry the germ, and prevent their ſprouting: but if the oven is too hot, it will make the kernels ſhrink, and prevent their being peeled with any tolerable eaſe.

Were it only for the oil that theſe nuts afford, the trees which produce them would be worth ſome care. Mr. Evelyn ſays that one buſhel of them will yield fifteen pounds of peeled kernels, and that theſe will yield half that weight of oil, which the ſooner it is drawn, is the more in quantity, though the drier the nut, the better in quality. He adds, that the lee, or marc of the preſſing, is excellent to fatten hogs with. Certainly it would be good manure for land; as are the cakes of lin-ſeed, rape, &c. after the oil has been ſqueezed out of them. The green huſks boiled, without any mixture, make a good colour to dye a dark yellow. The kernel being rubbed upon any crack or chink of a leaking veſſel, ſtops it better than either clay, pitch, or wax.

The French are very fond of the kernels of theſe nuts ſcooped out of the ſhells before they are hardened, with a ſhort broad braſs knife; becauſe iron ruſts and communicates a diſagreeable taſte to the kernels. When ſcooped out, they are ſteeped in ſalt and water for a few hours before they are ſet upon the table, as well to take off all taſte of bitterneſs, as to make them peel with the utmoſt eaſe.

WANG-TOOTH, a jaw tooth.

WANT, a mole. *See the article* MOLE.

WANTY, a broad girth of leather, by which the load is bound upon a horſe.

WAPENTAKE, the ſame with what is commonly called a hundred, and generally uſed in the northern counties beyond the Trent.

WARBLES, ſmall hard tumours on the ſaddle part of a horſe's back, occaſioned by the heat of the ſaddle in travelling, or its uneaſy ſituation.

A hot, greaſy diſh-clout at firſt frequently applied, will ſometimes remove them. Camphorated ſpirits of wine are alſo very effectual for this purpoſe to diſperſe them, eſpecially if a little ſpirit of ſal ammoniac be added to the camphorated ſpirit. If there be a neceſſity for working the horſe, care ſhould be taken to have the ſaddle nicely chambered.

WARP, miſcarry, ſlink her calf.

WARREN, a franchiſe, or place privileged, either by preſcription or grant from the king, to keep beaſts and fowl of warren in; as rabbits, hares, partridges, pheaſants, &c.

By ſtatute 21 Edw. III. a warren may lie open, and there is no need of cloſing it in, as there is a park.

In the ſetting up a warren, great caution is to be uſed for the fixing upon a proper place, and a right ſituation. It ſhould always be upon a ſmall aſcent, and expoſed to the eaſt or the ſouth. The ſoil that is moſt ſuitable, is that which is ſandy; for when the ſoil is clayey or tough, the rabbits find greater difficulty in making their burrows, and never do it ſo well; and if the ſoil be boggy or mooriſh, there would be very little advantage from the warren, for wet is very deſtructive of theſe animals.

All due precautions muſt be taken, that the warren be ſo contrived, that the rabbits may habituate themſelves to it with eaſe. Many would have it, that warrens ſhould be encloſed with walls; but this is a very expenſive method, and ſeems not neceſſary nor adviſable; for we find but very few that are ſo, and thoſe do not ſucceed at all the better for it.

The dung of rabbits is a great fertilizer of uſeleſs lands, and Mr. Mortimer tells us that he has known vaſt crops of rye upon barren lands that have been old warrens well dunged by rabbits; and large oak and aſh upon the ſame, though the ſoil was very ſhallow.

WASTE, a name given to ſuch lands as are in no man's poſſeſſion, but lie common.

WATER, a ſimple, fluid, and liquid body, reputed the third of the four vulgar elements. Sir Iſaac Newton defines water to be a fluid ſalt, volatile and void of taſte: but this definition Boerhaave ſets aſide, inaſmuch as water is a menſtruum or diſſolvent of ſalts and ſaline bodies, which does not agree with the notion of its being a ſalt itſelf; for we do not know of any ſalt that diſſolves another. This laſt-mentioned philoſopher, therefore, defines water, a very fluid, ſcentleſs, taſteleſs, tranſparent, colourleſs liquor, which turns to ice with a certain degree of cold.

Though

Though water be defined a fluid, it is a point controverted among philoſophers, whether fluidity be its natural ſtate, or the effect of violence. We ſometimes find it appear in a fluid, and ſometimes in a ſolid form; and as the former, in our warmer climate, is the more uſual, we conclude it the proper one, and aſcribe the other to the extraneous action of cold.

Boerhaave, however, aſſerts the contrary, and maintains water to be naturally of the cryſtalline kind; ſince, whereever a certain degree of fire is wanting to keep it in fuſion, it readily grows into a hard glebe, under the denomination of ice. Mr. Boyle is of the ſame opinion. Ice, he obſerves, is uſually ſaid to be water brought into a preternatural ſtate by cold; but with regard to the nature of things, and ſetting aſide our arbitrary ideas, it might as juſtly be ſaid, that water is ice preternaturally thawed by heat.

If it be urged, that ice, left to itſelf, will, upon the removal of the freezing agents, return to water; it may be anſwered, that (not to mention the ſnow and ice which lie all ſummer on the Alps, and other high mountains, even in the torrid zone) we have been aſſured, that in ſome parts of Siberia, the ſurface of the ground continues more months in the year frozen by the natural temperature of the climate, than thawed by the heat of the ſun; and a little below the ſurface of the ground, the water which chances to be lodged in the cavities there, continues in a ſtate of ice all the year round; ſo that when, in the heat of the ſummer, the fields are covered with corn, if you dig a foot or two deep, you ſhall find ice and a frozen ſoil.

Water is generally divided into ſalt and freſh, with regard to the ocean and rivers. But, according to Dr. Shaw, it ſeems diviſible into as many different ſpecies, as the earth is into beds. Thus there are mineral waters of various kinds, according to the mineral ſubſtance they run over, and become impregnated with; tho' this impregnation ſometimes happens in the way of vapour and exhalation. Water, therefore, in general, may be as mixed a body as earth, and perhaps neither of them naturally exiſts in any conſiderable purity.

In a general analyſis of water, the doctor found,

1. That common warm water throws up numerous little bubbles, and explodes, in the exhauſted receiver of the air-pump; for which reaſon, water contains what may, by way of diſtinction, he called æther or ſpirit.

2. It contains a merely aqueous part, diſtinct from æther and the ſediment, as appears from diſtilled common water.

3. It contains a dry ſolid matter, which is either earthy or ſaline, as appears upon a full evaporation, and from the inſides of tea-kettles, which, after long uſe, are lined with a ſtony matter, that beats off in flakes or cruſty pieces.

Water is not only contained in the earth as in a reſervoir, but likewiſe floats in the atmoſphere. In both caſes, it is actuated, rarified, and put in motion by heat, ſo as to prove inſtrumental in producing effects. Thus it produces clouds, rains, dews, ſprings, and rivers. It refreſhes the earth, recruits vegetables, and is the ſupport of fiſh and other animals by conveying nutriment to all their parts. It is alſo the firſt and immediate inſtrument of fermentation, putrefaction, corruption, and change in all vegetable and animal ſubjects.

But the nature and uſes of water, will beſt appear from the following experiments:

1. That water is contained in many ſolid bodies, and to appearance in dry bodies, was proved thus: a piece of the hardeſt and drieſt bone being procured, and diſtilled in an earthen retort, with degrees of fire, a very large proportion of water, along with much oil and volatile ſalt, was obtained: whence it appears, that animal matters are reſolvable into the four chemical principles, water, oil, ſalt, and earth. This experiment holds true even of the oldeſt hartſhorn, the drieſt and hardeſt woods, earths, and pulverized ſtones.

Whence it alſo appears, that water may be concealed in ſolid bodies, and make a conſtituent part thereof: for it is not meant that water inſinuates itſelf into the ſuperficial pores of bodies, ſuch as wood, ſkins, &c. ſo as to ſwell them in moiſt weather, and leave them ſhrunk in dry; but that it remains permanently intermixed as an eſſential ingredient, or as a part of ſolid bodies. *See* BODY.

2. That water may be collected from the drieſt air, or in the hotteſt climate, was proved by the following experiment:

Half a pint of common water was put into a cylindrical glaſs, wiped perfectly dry on the outſide; then was added to the water, two ounces and three quarters of pulverized and dry ſal ammoniac; theſe were ſtirred briſkly together, whereupon the water floating in the external air, was, by the coldneſs thus produced, condenſed on the outſide of the glaſs as the ſalt diſſolved within, and trickled down in ſmall veins, into the ſhallow baſon ſet underneath to receive it.

This experiment holds in all climates and places of different heights where it has been tried; whence, by the law of induction, we may make it univerſal, till any contradictory inſtance appears. Thus, therefore, it may hold in the moſt parched countries and hotteſt ſeaſons, ſo as to afford an agreeable method of cooling potable liquors, and render them more refreſhing. For if the containing glaſs of the ſalt and water be ſet in any liquor, the liquor will be cooled thereby; and if any conſiderable improvement could be made in the contrivance, it is obſerved, that it might, in ſome meaſure, ſerve to ſupply the thirſty traveller in parched deſarts, and the ſailors with freſh water at ſea.

3. To determine the proportion of water contained in an aſſigned portion of the atmoſphere, we are directed by the following experiment:

Having by means of the air-pump, and an exact pair of ſcales, found the weight of a certain quantity of air, contained in a large glaſs veſſel, there was included therein a certain known weight of well dried potential cautery, whoſe property it is powerfully to attract the moiſture of the air. The veſſel was kept cloſe ſtopped for ſeveral hours; during which time, the potential cautery was grown wet, in which ſtate being weighed again, it was found conſiderably to increaſe; which muſt be either owing to the water attracted out of the air in the glaſs, or to a condenſation of the air itſelf into an aqueous fluid; for ſuch a fluid might now by diſtillation be obtained from the matter thus run per deliquium.

It is obſerved that there is room to ſuſpect, that if this experiment were made in perfection, a weight of water almoſt equal to that of the air included in the veſſel, might be thus obtained, which might prove an extraordinary diſcovery, and ſhew what ſome have endeavoured to prove, that the matter of common air is little more than water.

4. That an earthy ſubſtance is naturally contained in water, was proved as follows. Three ſeveral glaſſes were filled with pure rain-water, ſpring-water, and Thames-water, and ſuffered to ſtand, cloſe covered, for ſome days before they were exhibited. There was an earthy ſediment then depoſited in all the three, but moſt in the Thames-water, the ſediment whereof was not only larger, but alſo more foul and muddy than in the rain-water; though here, alſo, it was dirty, perhaps, becauſe not carefully collected; whereas, in the pump-water, it was white, ſcaly, flaky, and ſhining, like fine ſpangles of talc. This experiment is alſo univerſal, ſo far as it has been tried with care, and holds true of the waters of all ſpecies and all countries, particularly in thoſe called mineral waters, from which an earthy ſubſtance may uſually be precipitated by art, in a conſiderable proportion.

Certain experiments carefully made, and repeated, ſhew that the terreſtrial matter naturally contained in water, has a principal ſhare in the growth and increaſe of vegetables; all the plants that thrive in water appearing to enlarge their bulk in proportion to the earthy matter they draw from the water. Whence pure elementary water ſeems but a kind of vehicle to convey this nutrimental or ſubſtantial part, and depoſite it in the veſſels through which the water moves, in order to its general exit at the ſurface of vegetables. But we are not here to exclude the inſtrumental efficacy of the two other elements, fire and air. And this appearing to be the general office of water, in the whole animal and vegetable kingdoms, viz. the conveyance or diſtribution of the alimentary matter to all their parts, it may be proper to conſider its phyſical properties, which would wonderfully fit it for this office.

The figure of its component parts appears to be ſmooth and ſpherical, like thoſe of quickſilver; whence it becomes extremely moving and penetrating. Thus it readily enters the pores of wood, leather, ſkins, chords, muſical ſtrings, &c. thus likewiſe it becomes capable of moving and agitating particles of matter leſs active than itſelf, and ſo proves the more immediate phyſical agent of fermentation, putrefaction, ſolution, &c. and thus it alſo conveys earthy and ſaline matters through our filtres of paper, ſtone, &c. and even raiſes ſome proportion of them in diſtillations. Its particles likewiſe appear to be extremely minute, and ſo have a large ſhare of ſurface.

Hence water is admirably fitted for a ſolvent, or for readily entering the pores of ſalts, and coming into full contact with all their particles; and thus it will paſs when air cannot, on account of its moiſture, or lubricating power, whereby it faſtens mucilaginous matters, and will therefore ſoak through the cloſe pores of a bladder.

The ſpecific gravity of water, and conſequently its goodneſs by its lightneſs, are to be directly judged of by the hydroſtatical balance. This experiment is a good ſubſtitute for ſeveral other ways of examining the purity and goodneſs of waters both common and mineral; for it appears by numerous inſtances, that light waters are, *cæteris paribus*, the beſt, pureſt, and wholeſomeſt. That water is accounted beſt and wholeſomeſt, which is not only the lighteſt and freeſt from earthy ſediment, but that which is moſt ſpiritutous; and theſe properties are uſually found in pure rain-water; that being naturally diſtilled from the ocean and rivers, or by the heat of the ſun raiſed up into the atmoſphere, from whence it is returned much after the manner of common diſtillation.

From the preceding, and other experiments of Dr. Shaw, made upon water, he deduces the following axioms:

Firſt, we have ſeen, That water is naturally contained in ſome of the drieſt and hardeſt bodies, and in the drieſt air. 2. That itſelf naturally contains an earthy ſubſtance. 3. That it is the proper menſtruums of ſalts, diſſolving more of one, and leſs of another. 4. That one good ſign of its purity and wholeſomeneſs is its levity. 5. That the ingredients of a mineral water may be diſcovered by chemical expedients: and, 6. That mineral-waters are imitable by art from ſuch diſcovery.

Secondly, That water is of infinite uſe in all the works both of nature and art, as without it there could be no generation, nutrition, or accretion, performed in any of the animal, vegetable, mineral, marine, or atmoſpherical regions. The blood could not flow in the veins, the ſap in the veſſels of vegetables, nor the particles of minerals concrete and grow together, without water. It is this that makes the largeſt part of our blood, our drink, and other aliments. There could be corruption, fermentation, or diſſolution, carried on without it; no brewing, no diſtilling, no wines, no vinegar, no ſpirits, made without it.

Thirdly, That we meet with water under an infinite variety of forms, and in an infinite variety of bodies, as that of air, vapour, clouds, ſnow, hail, ice, ſap, wines, blood, fleſh, bone, horn, ſtone, &c. through all which it ſeems to paſs unaltered, as an agent or inſtrument that ſuffers no alteration by re-action, but remains capable of reſuming the form of water again upon occaſion.

Fourthly, That water, in it own common ſtate, appears to be a combination of all the elements together, as containing a quantity of fire, which keeps it fluid; a quantity of air, and a quantity of earth: whence it can be no wonder that water alone, as it appears to the ſenſes, ſhould ſuffice for vegetation in ſome caſes, where little earth is wanted, or for ſupporting animal and mineral life, where no great degree of nutriment is required; and hence it proves a gluten, or cement, to ſome bodies, and a ſolvent to others: thus it conſolidates brick, plaſter of Paris, ſtone, bone, &c. but diſſolves ſalts, and ſubtile earths approaching to ſalts, and becomes the inſtrumental cauſe of their action.

Fifthly, That water conveys nouriſhment, or a more fixed and ſolid matter to the parts of vegetables, where having depoſited it, the finer fluid perſpires into the atmoſphere, which gives us the phyſical cauſe of the dampneſs and unwholeſomeneſs of woody countries, as they remarkably find in America. For all large vegetables act after the manner of forcing-pumps, and continually draw in large quantities of water at their roots, and diſcharge it at their leaves, which intimates a method of collecting water in dry countries, and likewiſe of making ſalt-water freſh.

Sixthly, That the water in paſſing through plants, after having depoſited its more terreſtrial part, does not always go off pure, but impregnated with the finer effluvia, or more ſubtle particles of the vegetable; thus, making an atmoſphere round every plant, according to its nature odoriferous or otherwiſe, which ſupplies us with a rule for procuring the odoriferous waters of vegetables by diſtillation.

Seventhly, That the particles, not fine enough to go t hus along with the water, are left behind upon the ſurface

ſurface of the leaves and flowers of plants, being now thickened or ſtrained from the moiſter plants, and remaining in the form of honey, manna, gums, balſams, &c. according to the nature of the vegetable. And hence appears the phyſical cauſe of plants proving more odoriferous and ſweet when the weather is both warm and moiſt, as immediately after a ſummer's ſhower.

Eighthly, That the chemical operator ſhould form to himſelf an hygrometer, for the ſervice of his elaboratory, to determine the proportion of water at all times contained in the air, which continually mixes with his preparations, differently augments their weight, and promotes or hinders many of his operations.

Ninthly, That pure water makes the largeſt part of mineral-waters, where it is impregnated as a menſtruum, with ſeveral ingredients that it diſſolves or drinks up in its paſſage through the earth.

Tenthly, and laſtly, The preceding enquiry affords conſiderable light for diſcovering practicable ways of making ſea-water freſh and potable, and of preparing waters by art, ſo as to render them fitter for the common œconomical uſes, and the ſervice of many particular arts.

But though water is abſolutely neceſſary to the growth of vegetables, and experience hath long evinced the great advantages ariſing from the overflowing of paſtures, it is but of late years that this very profitable improvement is become pretty general in England; nor is it, as Mr. Worlidge obſerves, "yet carried to near the perfection it might be advanced unto, if the following obſtructions were removed.

"1. The ſeveral intereſts that are in lands bordering on rivers, hinder very much this improvement, becauſe the water cannot be brought over ſeveral quantities of land ſo circumſtanced, but through the ground of ignorant and croſs neighbours, who will not conſent thereunto (though for their own advantage alſo) under unreaſonable terms; and ſome will not at all. Others, again, are not, by law, capacitated for ſuch conſent.

"2. A great and pernicious impediment to this improvement is the mills that ſtand on many fruitful ſtreams; prohibiting the laborious and ingenious huſbandman to receive the benefit and advantage of ſuch ſtreams and rivers, which carry in their bowels much wealth into the ocean, while the mills themſelves yield not a tenth of the profit to the owners, that they hinder to their neighbours, and their work may be as well performed by the wind, as by the water.

"3. Another grand impediment is the ignorance of the countrymen, who are commonly poſſeſſed with a fooliſh opinion, that the water leaves all its fatneſs on the ground it firſt flows over, and therefore will not benefit the next; which is moſt untrue; for I have ſeen meadows ſucceſſively drowned with the ſame water, to almoſt an equal improvement for many miles together. It is true, the water leaves behind it a great part of the fatneſs whirh it hath waſhed from the hills and high-ways in the time of great rains: but we find by daily experience, that meadows are fertilized by overflowing, as well in clear and dry weather, as in rainy, and that to a very conſiderable degree. The cleareſt and moſt tranſparent ſtreams will improve even ordinary lands, ſo much as to render them very fertile meadows.

"4. From a greedy and covetous principle, the graſs is ſuffered to ſtand ſo on the watered meadows, that it becomes much diſcoloured, grows haulmy, and is neither ſo toothſome nor ſo wholſome, as that of unwatered meadows.

"5. The former of theſe impediments might eaſily be removed by a law, which would be of very great advantage to the kingdom in general. The latter can be remedied only by the example of ſuch induſtrious and worthy perſons as underſtand better things: the generality of the world being rather introduced to an ingenious and profitable enterprize by example, than by precept: although ſome are ſo ſordid and ſelf-willed, that neither apparent demonſtration, nor any convincing argument whatſoever, can divert them from their bias of ill huſbandry."

The induſtrious Swiſs, ſenſibly attentive to every means of benefiting their deſervedly cheriſhed country, have thought this branch of huſbandry of ſufficient importance to propoſe it for the firſt premium offered by their truly laudable Society at Berne, for the year 1760: and I gratefully confeſs myſelf indebted to the diſſertations produced thereby, for ſeveral of the following remarks.

Water not only acts as a vehicle to the nouriſhment of plants, but alſo carries with it many particles which enrich the ſoil; eſpecially after heavy rains. It then depoſits a fertiliſing ſediment, which turns the mould to a blackiſh colour. The common ſaying, that watering makes the ſtones diſappear, is true; not ſo much from their ſinking into the earth, as from their being covered by the new ſupply of mould brought by the ſlimy muddy water, particularly after great rains. Watering likewiſe promotes the putrefaction of every vegetable and animal ſubſtance found in the earth, and thereby contributes greatly to meliorate the ſoil underneath the ſward.

Plants which grow on dry paſtures contain richer and more nouriſhing juices, than thoſe which grow in moiſt places. Care ſhould therefore be taken, that the quantity of moiſture brought upon the paſture, be only ſuch as ſhall give vigour to the plants, without over-charging their veſſels. In order to do this, every part of the paſture ſhould be watered equally, and as little water as poſſible ſhould be ſuffered to go where the land is naturally moiſt.

Extreme heat ſhould alſo be avoided in watering; becauſe heat draws the moiſture too haſtily up into the plant, which is thereby filled with a watery juice, and rendered of ſo tender a texture, as eaſily to be killed afterwards by drought or cold.

If the ſpring proves dry, paſtures may be watered as ſoon as the froſty ſeaſon is over; and this may be continued till the graſs begins to ſhoot. But if the winter has been ſevere, and the earth remains moiſt, no current of water ſhould be admitted, till the earth looſened by the froſt is ſettled, and the ſurface become pretty dry: for even the gentleſt ſtream would carry off the fine mould looſened by the froſt. After that the graſs has begun to ſhoot, and the weather is become mild, the water ſhould be adminiſtered more ſparingly; that is to ſay, in ſuch proportion only, as juſt to puſh the graſs gently on, till it has made ſuch a covering as can ſhelter the earth from the too great power of drying winds, or of a ſcorching ſun. Watering ſhould afterwards be uſed with great caution, and only in caſe of extreme drought; nor even then, unleſs the water be perfectly clear and ſweet, leſt it ſhould foul the graſs, or give it a bad taſte. If it be admitted ſparingly before the hay is cut, it will make the graſs ſtand the better to the ſcythe.

For a little time after the hay is made, the water ſhould be admitted only in the night; becauſe the weather then

generally is very warm: for it is obſerved, that rain which falls with a hot ſun, or a hot ſun that comes on a heavy dew, is prejudicial to plants. Watering, under the ſame circumſtances, will have the ſame effect to prevent which, the prudent huſbandman will let in his water only in the evening, and will withdraw it again before the ſun gets up. It is continued at this ſeaſon only till the graſs begins to ſhoot vigorouſly; and in caſe of very great drought it may be repeated, but very ſparingly.

If a ſecond crop of hay is made, the water may be uſed more freely; as the weather is then become cooler, and the earth is generally very dry. This flooding will bring up a plentiful after-math. If the ſecond crop of graſs is fed off, the watering ſhould be renewed in the ſame manner: only care ſhould be taken not to ſuffer cattle to feed on the ground while the water is upon it, becauſe their poaching would deſtroy the roots of much of the graſs, and leave the ſurface uneven; which ſhould be avoided in a paſture.

The latter end of autumn is the ſeaſon in which watering is the longeſt continued: and conſidering the dryneſs and parched ſtate of the earth at that time, this practice ſeems rational: for the water then, not only ſupplies the moiſture wanted in the earth, but it diſſolves every ſubſtance ſoluble in water, and thereby converts to an additional manure, what might otherwiſe have remained long in its original ſtate. Care ſhould, however, be taken, to drain off the water before the ſeaſon of ſtrong froſts is expected; becauſe froſt is obſerved to deſtroy all kinds of vegetables much more when the plants are full of ſap, than when they are in a dryer ſtate. We may eaſily comprehend that it muſt have this effect, when we conſider with what force it breaks every veſſel containing water expoſed ſo as to be frozen: for froſt dilates all fluids to ſuch a degree, that the veſſels in which they are muſt be broken thereby. Hence it is that ſucculent plants ſoon become a putrid maſs after a hard froſt: and thus it is that the ſtrongeſt trees are ſometimes burſt with a loud report.

When the water is brought to the deſired height, the main channel ſhould be cut, with ſuch a deſcent as only juſt to keep the water in a gentle motion. That channel ſhould be made in the higheſt part of the paſture, and proportioned to the quantity of water neceſſary to be introduced. If a hollow intervenes between the place at which the water is brought into the field, and another riſing ground in that field; it will be worth the farmer's while to convey it a-croſs that hollow, by pipes made of wood, or any other ſubſtance, laid either horizontally over that hollow, or underneath it. The motion of the water in this horizontal channel ſhould be different, according to the quality of the ground. If it is a ſtrong earth, the channel may be cut nearly horizontally: but if it is a light looſe ſoil, a quicker current ſhould be given to the water, in proportion to the degree of lightneſs of the earth; or great part of the water will otherwiſe be loſt, by ſinking into it. In a light ſoil of this kind, it may be proper to line this main channel with brick or ſtone, well cemented with lime, to hinder the water from eſcaping through the crevices; or at leaſt to cover it with clay well rammed. As to the degree of deſcent moſt proper for the main channel, in order to give a current to the water, M. Bertrand, to whom we owe one of the ingenious diſſertations on this ſubject in the memoirs of the Berne Society, obſerves, that Vitruvius required ſix inches in an hundred feet, which is a great deal too much: but that the moderns, who have made the moſt exact experiments in this reſpect, are ſatisfied with two inches in ſix hundred feet, when they cannot have more, and recommend particularly the avoiding of all ſharp angles in the winding of the channel, and the making of its bottom quite ſmooth and even. He adds, that this is nearly the declivity of the aqueduct of Rocquancourt, by which the water is conveyed to Verſailles; the diſtance there being three thouſand four hundred yards, and the ſlope, in all, only three feet.

The main channel ſhould be of breadth, rather than depth, ſufficient to receive all the water that is intended to be conveyed through it, and that breadth ſhould leſſen gradually as the water is carried off in leſſer channels, in order that the water may preſs into thoſe ſmaller ducts, which are to iſſue all along from the chief. The leſſer channels ſhould be as ſhallow, and as numerous, as can be: for the more equally the water is diſtributed over the graſs, the greater will be the improvement. They ſhould be made particularly wherever the water collects itſelf into a ſtream: for though cutting ſo much turf may ſeem to waſte a great deal of land, yet it proves not ſo in the end; becauſe the quicker the water runs over the graſs, the more it benefits the paſture.

To keep the channels in repair, they ſhould be frequently cleaned, eſpecially after every cutting of the hay. The ſlime then taken out of them ſhould be ſpread upon the paſture, and the next growth of the graſs will be greatly improved thereby. Care ſhould alſo be taken to have drains to carry off the water, ſo that none of it may ſtagnate upon the land.

The beſt way of watering a flat meadow, which is uſually ſurrounded with a ditch, is to ſtop the out-let of the ditch, and, by bringing in a quantity of water, to overflow the whole meadow, for ſuch time as ſhall be judged neceſſary to moiſten the earth ſufficiently: but the water ſhould not be continued upon it ſo long as to wither the graſs. If this can be done in a rainy ſeaſon, it will be ſo much the better; becauſe the water will then be loaded with the enriching mud and ſlime waſhed down from the higher grounds.

The firſt heavy rains which fall in the latter end of the autumn, and which carry with them the rich particles of putrified animals and plants, are thought to be more fertilizing than at any other ſeaſon of the year, and are therefore brought into the paſture, as often as the abſence of the cattle fed on them will permit.

The next beſt to rain, is clear and ſweet ſpring water, flowing from a copious ſource. Here it is generally objected, that ſpring water is hard, and therefore not fit for the nouriſhment of plants. But Dr. Home, who judges otherwiſe, expreſſes himſelf thus on this very occaſion. "Is not hard water more nouriſhing for vegetables than ſoft water? I imagine that the ſalt of vegetables enters their veſſels in ſuch a form as hath the ſalt which is found in hard waters. The ſalt of hard waters ſeems likewiſe to be of the nitrous kind, of which the nouriſhment of plants is alſo ſuppoſed to be. This query thwarts the general opinion; for no gardener will make uſe of hard water, if he can avoid it. I watered ſome plants with it, and thought that they grew better than thoſe which were watered with ſoft water."

This is confirmed by an ingenious correſpondent of the Berne Society, who made ſeveral experiments on the qualities of different waters, and found that their greater or leſs hardneſs made very little difference in their effects,

when

when uſed for watering of paſtures. The water of an excellent ſpring, which, upon trial, was found to be hard, fertilized greatly the paſture upon which it was let in.

Spring water may be uſed later in the winter, than any other, becauſe, being warm, a mild froſt will not freeze it, even when expanded on the paſture. It ſhould however be turned off ſoon enough to let the earth become a little dry before ſevere froſts ſet in. It may likewiſe be uſed earlier in the ſpring, than other waters, and to better advantage, by reaſon of the warmth which it communicates to the ground where it flows: and it becomes extremely proper in the ſummer, becauſe it cools during the night (the only time for watering at that ſeaſon) the heated ſoil, and graſs ſcorched by the power of the ſun.

The equal warmth of ſpring-water, is what renders it peculiarly uſeful for watering paſtures. The laſt quoted correſpondent of the Berne Society tried its heat, in Swiſſerland, on the twenty-ſixth of May, when the earth had been very little warmed by the ſun, after a long winter's cold. He then found M. de Réaumur's thermometer, placed in the ſpring of water, ſtand at eight degrees and a half (equal to forty-ſeven and a half of Farenheit's) above the freezing point. On the fifth of July, in the evening, when the heat of the air was very great, Réaumur's thermometer, again placed in the ſpring, ſtood at nine degrees and a quarter (equal to forty-nine of Farenheit). He afterwards tried whether the warmth of the ſpring was conſiderably increaſed towards the end of the ſummer, when the earth was extremely heated: but even then, Réaumur's thermometer ſcarcely reached ten degrees (equal to about fifty of Farenheit's). By this we ſee, that ſprings which yield a full and conſtant ſtream vary very little in their degrees of warmth.

For the ſame reaſon it alſo is, that a perpetual verdure reigns around ſuch ſprings, even during the hardeſt froſt; and if their water could be preſerved from freezing when ſpread over a field during the winter, it would be right to let them in upon paſtures in that ſeaſon: but as they ſoon loſe their heat when diſperſed over the graſs, this is by no means adviſable.

Experience has taught the inhabitants of the Alps (and the ſame will hold equally true in all mountainous countries), that it is not adviſable to water paſtures with the floods which ariſe from melted ſnow, or with the water of rivers fed thereby. One reaſon which ſeems to render the water that deſcends from mountains perpetually covered with ſnow the leſs uſeful for watering paſtures, is, that as all vegetation is at a ſtand in ſuch places, no vegetable matter can be mixed with this water; and it therefore cannot communicate the fertility which ariſes from waters fraught with thoſe rich ſubſtances.

We are frequently told of correcting the crudity of water, by making it turn a wheel, or putting it otherwiſe into violent motion: but I know not what good effect this can have.

What are commonly called barren ſprings, are ſometimes corrected by mixing dung with their water in ponds made higher than the paſture intended to be watered. Yet this, though an old cuſtom, is liable to ſome objections; one of which, in particular, is, that the water will depoſit its richneſs on the firſt part of the paſture over which it flows, and therefore improve the graſs very unequally. But if dung has this effect, it will anſwer equally well, if it be ſpread upon the land. Care ſhould, indeed, be taken, that the current of the water be very ſlow over a paſture newly dunged; becauſe the fertilizing particles of the dung may otherwiſe be carried off by the ſtream, before they can have had time to penetrate into the earth.

When dung, marle, or lime, is laid on a paſture which has a conſiderable deſcent, the beſt way is to lay a larger proportion on the higher parts; becauſe the common rain water will waſh ſome of their richer particles down to the lower.

As clayey ſoils retain water, and by that means chill the plants growing on them, they are the leaſt fit for watering of any. If the water abides on them, they become poachy; and when dried again, they gape, and become ſo hard that no plant can pierce them. Some ſenſible farmers have likewiſe obſerved, that their clayey lands have always yielded leſs graſs in wet years, than when the ſeaſon has been dry; which is a manifeſt proof that a ſoil of this kind does not admit of watering, unleſs it be a little, in caſe its ſurface is become hard after the hay has been taken off, or when the graſs is ſhort. Such lands are fitter for arable, if their ſituation permits it.

Hazel earth, which is a loam mixed with gravel, and of a clayey nature, is the ſtrongeſt ſoil that can be watered with propriety; and that this has been ſurprizingly benefited thereby, is evident from ſeveral inſtances given in the Memoirs of the Berne Society, even of large tracts of ſuch ground that have been vaſtly improved by this means: but I ſhall mention here only the following.

"In the ſummer of 1758, part of the paſture ground belonging to a farmer in Swiſſerland was ſo entirely covered with ſtones and gravel, by the ſudden overflowing of a ſtream, that it looked like a bank of ſand. As the removing of this quantity of ſtones and gravel would have coſt a great deal of labour and expence, the owner of the land carried off only the largeſt ſtones, and threw over the gravel a reddiſh earth taken from a neighbouring hill; but ſo thinly ſpread, as only to fill the interſtices between the pebbles, without entirely covering them. He then ſowed this ſpot with hay ſeeds, and let in upon it the waters of an adjacent ſpring and a neighbouring rivulet. Theſe waters were let in ſparingly at firſt, till the graſs began to appear, and after that they were flowed more abundantly. The conſequence of this prudent conduct was, that the graſs thus raiſed bore cutting once the firſt year, and after having been mowed twice in the ſecond, promiſed an excellent after-math at the time when this account was written, which was in the beginning of the autumn of that ſecond year. The very firſt year's crop grew ſo prodigiouſly, that the graſs was lodged, even though the pebbles were then felt under foot, if one trod upon it." *See the article* MEADOW.

When the land is above the level of the adjacent water, recourſe muſt be had to ſome engine to raiſe it to a proper height, in order to overflow it; though this will be attended with a very conſiderable expence, eſpecially at firſt.

The oldeſt inſtrument uſed for this purpoſe is known by the name of Archimedes's water ſcrew, and is thus deſcribed by Mr. Emerſon.

C *p* D (Plate XXVII. Fig. 1.) is a cylinder which turns upon the axis C D. About this cylinder there is twiſted a pipe, or rather ſeveral pipes, *no*, *pq*, running ſpiral wiſe from end to end. This cylinder is placed higher at one end, D, than at the other; and its uſe is to ſcrew up the water from the lower end to the higher. A B is a river running

running in the direction A B. *a*, *b*, *c*, *d*, are ſeveral floats fixed to the cylinder. E F is the ſurface of the water. As the cylinder ſtands in an inclined poſition, the upper floats *a b*, are ſet out of the water, and the under ones *c d* within it: ſo that the water acts only upon the under ones *c*, *d*, and turn about the cylinder in the order *a*, *b*, *c*, *d*. By this motion, the water taken into the ſpiral tubes at the low end is, by the revolution of the cylinder, conveyed through theſe pipes, and diſcharged at the top into the veſſel G. If A B is a ſtanding water, there is no occaſion for the floats *a b c d*; and then the cylinder is to be turned by the handle at D. Inſtead of the pipe, a ſpiral channel may be cut round the cylinder, and covered cloſe with plates of lead. The cloſer theſe ſpiral tubes are, the more water is raiſed: but it requires more force. Alſo the more the cylinder leans, the more water it carries; but to a leſs height.

Where a conſiderable quantity of water is to be raiſed, a greater force is requiſite, than can be applied to ſuch a handle. Her royal highneſs the princeſs dowager of Wales has cauſed an inſtrument of this kind to be erected at Kew, by the ingenious Mr. Smeaton, and by means thereof a ſufficient quantity of water is ſupplied, for all the ponds, and other uſes, in that elegant and extenſive garden: but it is there worked by horſes.

The moſt common engine for raiſing water is the Perſian wheel, of which Mr. Worlidge gives the following deſcription.

"This wheel is made much after the manner of that of an under-ſhot mill, viz. with a double ring, into which are let two pins, on which the floats are faſtened. Theſe floats are made hollow; the half that is the moſt remote from the wheel, holds the water which is taken in at the open place, above the middle of the back of the float, and as the wheel goes round, and the float laden with water riſes, ſo the water, by degrees, tends towards that part of the float which is next the wheel, and as the float ſurmounts the ciſtern or receiver, the water empties itſelf into it, every float ſucceeding the one the other, emptying itſelf into the receiver: ſo that if one float contain a gallon of water, and there be thirty floats on the wheel, at one motion round it delivers thirty gallons of water into the ciſtern. Such a wheel will be about fifteen foot diameter, the floats are eighteen inches diſtance, and will deliver the water at eleven or twelve foot above the level of your ſtream, and will go four times round in one minute, and carry up about one hundred and twenty hogſheads of water in an hour, with twelve or eighteen inches penning or ſtopping of but an ordinary current of water which will water very well thirty or forty acres of land: for if your land be cold and clayey, too much water does it hurt; and if it be light, warm, or ſandy, a little water does it much good. It is alſo to be obſerved, that this motion is conſtant, and will laſt many years without repair, ſo that it ſtand not ſtill, for one ſide to dry and wax lighter than the other: alſo obſerve, that the ſlower it moves, the better it delivers the water.

"The view of this wheel we have in Plate XXVII. Fig. 2. *aaaa* ſignify the wheel; *b*, the ciſtern that receives the water; *c c*, the trough ſtanding on treſſes, that conveys the water from the ciſtern to the place you deſire; *d*, the hatch, or pen-ſtock that bays up the water to a reaſonable height, under which the water drives the wheel; *e* (Fig. 3) one of the floats preſented open to your eye, apart from the wheel; *f*, the place that is to receive the water; *g*, the open place out of which the water iſſues; *b b*, the two pins or ledges riveted on to the foreſide of the float, and wherewith you are to fix the float to the two rings of the wheel. Theſe, or ſuch like wheels, are much uſed in Spain, Italy, and France, and are eſteemed the moſt eaſy and advantageous way of raiſing water in great quantity, to any height within the diameter of the wheel, where there is any current of water, to continue it in motion, which a ſmall ſtream will do.

"How many acres of land lie on the declining ſides of hills, by the ſides of rivers, in many places where the water cannot be brought unto it by any ordinary way? yet by this wheel placed in the river, may the land be continually watered, ſo far as is under the level of the water when raiſed."

Inſtead of raiſing the water by means of the hollow floats placed around the outer circumference of the rim of the wheel, as here deſcribed; M. Belidor propoſes, for wheels of this kind, to raiſe it in buckets placed at equal diſtances upon the ſide of the rim of the wheel, and ſuſpended by a pin, upon which they play, as at A Fig. 4. When, by the rotation of the wheel, one of theſe buckets comes to B, which is the ſummit of the wheel, the upright piece D, which is faſtened to the ſide of the trough C, turns that bucket upon its ſide, and thereby makes it empty itſelf into the trough C, from whence the water is diſcharged into a receiver at E.—As theſe buckets keep full of water till they are carried up to the top of the wheel, where they are turned over, a much greater quantity of water may, undoubtedly, be raiſed by them, than can be by the floats of the Perſian wheel, from which much muſt be ſpilled as it is carrying up. The ſize of theſe buckets ſhould be adapted to the force of the current of the water which they are to take up.

Another wheel for raiſing water, though not ſo great a height, is repreſented in Fig. 4. This engine was firſt invented by M. de la Baye of the Royal Academy of Sciences at Paris, and is now uſed with great ſucceſs by the honourable Mr. Hamilton, at his ſeat at Pain's-hill in Surry, where that gentleman has ſhewn how far a barren ſpot may not only be rendered uſeful but even an ornament to the adjacent country.

This machine conſiſts of a wheel whoſe ſize is adapted to the height to which it is intended to riſe the water. A perſpective view of this machine is repreſented Fig. 5. and its internal parts Fig. 6. The wheel turns upon its axis at A, and has ſeveral curved pipes, B, C, D, E, fixed to it, as repreſented in the figures. The mouth of each pipe aſcends as the wheel is turned round by the ſtream, in the direction indicated by an arrow, and the water deſcends from C towards F, till it reaches the hollow axis. A, A, from the opening at the end of which it is diſcharged into the trough G, and thence conducted by troughs, as H, or other channels, to whatever place it may be wanted.

But if there be a neceſſity to raiſe the water higher than the axis of the wheel, we would recommend an ingenious machine, uſed for above twenty years at Zurich, for ſupplying a large dye-houſe there with water from the Limmat, and of which a deſcription in the German language appeared in the third volume of the Zurich Acts, from whence the following account is tranſlated.

The wheel itſelf differs little in appearance from other water-wheels. Its diameter, excluſive of the ladle-boards, is not quite three feet. It is coated all over with tin plates, and

PLATE XXVII

Fig 9.

and forms a ſhort cylinder, or rather drum, of the above diameter, and one foot thick. On its periphery the ladle-boards are fixed, as in other under-ſhot water-wheels, and by means of which it is put in motion by the ſtream. It turns on a hollow axis (like the laſt machine) of proportional thickneſs and length, and has one of its flat ſides applied againſt a projection, or ledge, made round the axis, to which it is preſſed cloſe, and held faſt by a wedge driven through the axis at the other ſide. That part of the axis which paſſes through the wheel is ſquare, that the wheel may not ſlip, or be able to turn, without turning the axis with it: the remaining part of it is round. The wheel is hung in the water to about one third of its height, and ſupported in a moveable frame, ſo that it can be lowered, raiſed, or even taken out of the water at pleaſure. In the periphery of the wheel are holes, by which the water enters. The axis turns as uſual, on two pivots, one of which is of braſs, conſiderably larger than the other, and hollow from end to end, communicating with the canal in the axis. The hollow pivot, which may be conſidered as a braſs pipe, has its end fitted cloſe to a leaden pipe, in which it turns. The leaden pipe, by a double bending, is confined to the wall of the dye-houſe, where it is bent perpendicularly upwards, and riſes along the wall to the height of ten feet above the axis; it is there bent again under the eaves, and continued into the dye-houſe itſelf.

The ſingular and remarkable operation of this little wheel depends ſolely on its internal ſtructure. The water entering at the circumference of the wheel, runs in a ſquare ſpiral canal, which paſſes round the wheel, and conſiſts of a number of circumvolutions, within one another, like the ſpring of a watch, till at length it comes into the axis. A neceſſary condition here is, that each of the inner circumvolutions be of the ſame magnitude with regard to their content, as the outer one; or that the width of the ſpiral canal be gradually enlarged in each circumvolution, in proportion as the diameter diminiſhes; that is, the bore of each of the inner ſpirals muſt be to the bore of the outer one, as the diameter of the latter is to the diameter of the former.

The wheel thus furniſhed with its ſpiral canal, is to be hung ſo deep in the river, that half a ſpiral, at leaſt, may, in each revolution, be filled with water. To keep it in this ſtate it would be neceſſary to immerſe it to the axis, or further: but as its motion, at ſuch a depth, would be extremely ſlow, a kind of ſcoop is made at the outer opening of the ſpiral pipe, which takes up ſo much water at once, as is ſufficient to fill the due proportion of the outermoſt ſpiral in one revolution. One half of the outer ſpiral being thus filled with water, the other half remains filled with air: as the wheel turns the water and air paſs into the ſecond ſpiral, then into the third, fourth, and ſo on, till a ſufficient number of turns brings the water and air to the axis, from whence they paſs into the upright pipe, as already mentioned: thus the entrance and diſcharge of water continue without intermiſſion, ſo long as the wheel is kept in motion. When the wheel ſcoops up juſt the proper quantity of water, and turns with due velocity, the water may be forced up in the perpendicular pipe to a height equal to the ſum of the diameters of all the circumvolutions of the ſpiral canal.

If we conſider the operation of this machine, we ſhall eaſily ſee the neceſſity of the inner circumvolutions being made to widen in the proportion above-mentioned; and that, without this condition, the water paſſing from the large outer ſpiral, would be crouded and retarded in the inner, and in great part forced back.

It is alſo obvious that juſt half of one of the ſpirals muſt be filled with water at each revolution, for if leſs be taken in, there will be a diminution in the quantity delivered, and if more, it will be preſſed too much together, and its quantity alſo diminiſhed.

The velocity with which the wheel moves, or the number of revolutions it makes in a given time, is another eſſential point in regard to the quantity of water, and may conſiderably influence the quantity of water neceſſary to be raiſed. When this is known, and the height determined, it will be eaſy to conſtruct a wheel in ſuch a manner, as to anſwer the purpoſe intended.

We ſhall conclude our account of this ingenious contrivance, with the following directions for conſtructing it. The two flat ſides of the wheel ſhould be made of two ſtrong circular pieces of good oak, the inner ſides of which muſt be planed as ſmooth as poſſible, and fitted to one another; and to keep them from bending or warping, ſecured by pieces on the outſide. The plan of the ſpiral lines is repreſented in Fig. 7. Plate XXVII. Theſe ſpiral lines being marked out on the wood, a groove muſt be cut about a quarter of an inch deep, in order to make a channel for the partition, which muſt be formed of a thin piece of copper. The channel being filled ſomewhat more than half with good cement that will bear water, the piece of copper muſt be ſet in regularly, care being taken to keep the cement warm, or previouſly to heat the metal. The ſcoop alſo, which at every revolution of the wheel takes up a proper quantity of water from the river, may be made of the ſame metalline plate. The piece of copper for forming the partition muſt be cut at firſt exactly ſtrait, and of an equal breadth throughout. This work being finiſhed, the wheel muſt be put on the axis as far as the ledge made for it to reſt againſt, and cemented. The ſecond piece of wood requires little preparation: ſome cement muſt be ſpread all over it, and the whole ſurface covered with a thick piece of woollen cloth, which muſt alſo be done over with cement on both ſides: while the whole continues warm, it muſt be put on the axis, and preſſed cloſe to the other part of the wheel, ſo as to cover the as yet open ſide of the ſpirals. The two parts are held firm together, by means of a wedge or key paſſing through the axis, and a proper number of ſcrews, placed round the circumference: theſe ſcrews are ſtrong iron pins, ſomewhat longer than the wheel is thick, and a nut, when they are placed through the wheel, is ſcrewed on the other. Thus the inſide of the wheel, or drum is finiſhed. The diſpoſition of the ladle-boards, the ſhape of the axis, and the ſtructure of the frame by which the machine is ſupported, will be partly underſtood from what has been already ſaid, and more fully from Fig. 8. Plate XXVII.

It has been already obſerved, that the wheel in the Limmat is covered with tin plates; but this is of little or no conſequence. It is however adviſeable not to have one large opening, for the entrance of the water, but either a perforated plate, or a wire-grating nailed before it, in order to prevent weeds, or any other filth from paſſing into the ſpiral tube, and preventing, if not wholly ſtopping, the courſe of the water.

The frame or ſcaffold in which the wheel hangs, and the means of raiſing or lowering it in the river, without diſturbing the courſe of the water in the machine, deſerves particular notice. It is plain from Fig. 8. that the wheel

reſts on two arms, which, for the greater ſecurity, are bound together by croſs-pieces. At the fore-end they are both ſuſpended by iron chains, which paſs over a roller ſo as to be wound off or on: on the other end they move on two ſtrong joints or hinges. The communication of the leaden pipe, with the braſs one, or hollow pivot, at the end of the axis, is drawn on a larger ſcale, in Fig. 9. This pipe is bent cloſe by the pin, to a right angle, and goes horizontally along one of the arms of the frame as far as the hinge, (ſee Fig. 8.) where it is again bent to a right angle, oppoſite to the dye-houſe, and communicates in the ſame manner as the hollow pivot of the axis, with another horizontal pipe, in which it moves round freely, without any impediment to the paſſage of the water, in raiſing or lowering the wheel. This large pipe paſſes under a ſtage built along the wall of the dye-houſe, and thence up the wall, where it diſtributes the water in the manner repreſented in the figure.

But though water is ſo neceſſary to the growth of plants, yet in lands that abound with it, there is a neceſſity for conveying it away, the beſt methods for doing which the reader will find under the articles BOG, DRAWING, MOOR, &c.

WATER-FARCY, a diſeaſe incident to horſes, and is of two kinds; one the product of a feveriſh diſpoſition terminating on the ſkin, as often happens in epidemical colds; the other is dropſical, where the water is not confined to the belly and limbs, but ſhews itſelf in ſeveral parts of the body, by ſoft ſwellings yielding to the preſſure of the finger. This laſt kind uſually proceeds from foul feeding, or from the latter graſs and fog, that often comes up in great plenty with continued cold rains, and breeds a ſluggiſh viſcid blood. In the former caſe, I have ſeen the limbs and whole body enormouſly ſwelled, and very hard, the belly and ſheath greatly diſtended; which were as ſurprizingly reduced in four and twenty hours, by ſlight ſcarifications within ſide the leg and thigh, with a ſharp penkniſe, and three or four ſtrokes on the ſkin of the belly on each ſide the ſheath; from theſe ſcarifications there was a conſtant and ſurprizing large dripping of water, which ſoon relieved the horſe; when a few purges compleated his recovery.

In the other ſpecies of dropſy the curative intentions are to diſcharge the water, recover the craſis or ſtrength of the blood, and brace up the relaxed fibres throughout the whole body. To this end, purge once a week or ten days: and give intermediately either of the following drinks, or balls.

Take black hellebore freſh gathered, two pounds; waſh, bruiſe, and boil in ſix quarts of water, to four; then ſtrain out the liquor, and put two quarts of white wine on the remaining hellebore, and let it infuſe warm forty-eight hours; then ſtrain off, mix both together, and give the horſe a pint night and morning.

Take nitre two ounces, ſquills powdered, three drams, or half an ounce; camphor one dram, honey enough to form into a ball, to be given once a day alone, or waſhed down with a horn or two of the above drink.

Take of the leaves and bark of elder, of each a large handful; chamomile flowers half a handful, juniper berries bruiſed two ounces; boil in a quart of water to a pint and a half, to which add honey and nitre, of each one ounce.

Give this drink every night, or night and morning; and to compleat the cure, and ſtrengthen the whole body, give a pint of the ſubſequent infuſion every night and morning, for a fortnight, faſting two hours after it.

Take gentian root and zedoary, of each four ounces; chamomile flowers and the tops of centaury, of each two handfuls; Jeſuits bark powdered two ounces; juniper berries four ounces; filings of iron, half a pound: infuſe in two gallons of ale for a week, ſhaking now and then the veſſel.

Before we cloſe this article, we think proper to lay down the ſymptoms of an incurable farcy, that the owners of ſuch horſes may ſave themſelves unneceſſary expence and trouble in their endeavours to obtain a cure.

When a farcy by improper applications, or by neglect has ſpread or increaſed; or after long continuance reſiſted the medicines above recommended; if freſh buds are continually ſprouting forth, while the old ones remain foul and ill-conditioned; if they riſe on the ſpines of the back and loins; if the horſe grows hide-bound, and runs at the noſe; if abſceſſes are formed in the fleſhy parts between the interſtices of the large muſcles; if his eyes look dead and lifeleſs; if he forſakes his food and ſcours often, and his excrements appear thin, and of a blackiſh colour; if the plate, or ſhigh vein continue large after firing, and other proper applications: theſe ſymptoms denote the diſtemper to have penetrated internally, and that it will degenerate into an incurable conſumption: it is alſo moſt probable, that the whole maſs of fluids are tainted, and become incurable by art. *Bartlet's Farriery, page* 193.

WATTLE, a kind of hurdle formed with ſplit wood, and uſed for making folds for ſheep.

WAX, *or* BEES-WAX, a ſubſtance formed by bees from the farina of flowers. *See the article* BEE.

WAY-BREAD, plantain.

WEANEL, an animal newly weaned.

WEED, any plant growing in a field different from what the farmer intended.

There is not a field where we do not find ſome of theſe; they grow in the greateſt plenty on the richeſt ſoils.

Weeds will appear impediments to vegetation, if we conſider the following particulars.

They rob the plants we deſire to cultivate of their food; they prevent theſe plants from branching out from the root, and they leſſen the vegetable paſture in the land where they are ſuffered to grow.

Weeds are nouriſhed by the ſame food that would nouriſh uſeful plants; and therefore, when allowed to grow along with them, muſt rob them of part of their food. Although it is allowed, that the food of all plants is not exactly of the ſame kind; yet as plants ſuck in whatever juices, or ſmall particles of matter are touched by their roots, it may be juſtly ſaid, that all kinds deprive the earth of that vegetable food which would nouriſh others.

Experience convinces the farmer of the truth of this: for he finds, that his crop is bad in proportion to the quantity and kinds of weeds with which his land is infeſted.

Weeds cover the ſurface of the land on which they grow, and thereby, confining the plants we deſire to cultivate, prevent

prevent them from branching out from the root. For all plants, when confined by others at their ſides, inſtead of branching out, as ſome of them are inclined to do, make vigorous efforts to get above thoſe by whom they are confined.

Some perſons have attempted to ſhow, that corn never wants room to grow; and that it is the want of food alone which makes ſome plants decay, when they are ſet too thick. If this is true, weeds can do no harm to plants, by covering the ſurface, and confining them while they grow. But let a perſon caſt his eyes upon a plantation of any kind, and he will immediately obſerve, that where the plants are placed very near to each other, they ſtretch out chiefly to the length; and where they are placed at a greater diſtance, they grow not ſo much to the length, but more to the thickneſs, and branch out on all ſides. So that the proportion of nouriſhment which the plants receive, makes them grow either to the length principally, or to the thickneſs, and branch out, according as they are placed near, or at a diſtance from each other. The ſame thing happens, when there are many weeds growing amongſt corn. Some fields are ſo much infeſted with weeds, that, though no grain is ſown, the plants come up very thick. This obliges the farmer to give plenty of ſeed: in conſequence of which the ſurface is quite covered; and the plants of corn being confined by the weeds, inſtead of branching out from the root, and producing two or more ſtalks, as they are naturally diſpoſed to do, puſh up one ſtalk only, that ſo they may the more eaſily get above their rivals. The proportion of nouriſhment which they receive, makes them grow to the length, inſtead of branching out from the roots; makes them produce one ſtalk and ear only, inſtead of many. Experience confirms the truth of this. When land is rich, and at the ſame time much infeſted with weeds, the plants of corn grow tall enough; but ſeldom have more than one ſtalk.

Some kinds of weeds have great numbers of ſmall roots, which they extend to a great diſtance. Theſe roots bind the ſoil in ſuch a manner, as to leſſen the vegetable paſture; or rather, make it very difficult to enlarge it by tillage. It may be obſerved, that when a field is much infeſted with quickening graſs, the ſoil is ſo firmly bound together by the roots, that it is not poſſible to pulverize it. When ploughed, the earth of the furrow is turned over whole, and the harrows ſcarcely make any impreſſion upon it.

It is of great importance, therefore, to know how to deſtroy theſe uſeleſs and noxious plants, that ſo all the vegetable food in the ſoil may be applied to the nouriſhment of the uſeful plants we deſire to cultivate; that theſe uſeful plants may have room to extend themſelves, and branch from the root on all ſides; and that the vegetable paſture, which, by the rain that falls, and the natural weight of the ſoil, is always leſſening, may be the more eaſily enlarged.

Different kinds of weeds.

Plants are commonly divided into two ſorts; annuals, that is, ſuch as in one year come to perfection, carry ſeed, and die; and perennials, that is, ſuch as continue in life for more years than one. Annual plants are almoſt all propagated by the ſeed. Perennials are propagated, ſome by the ſeed, others by the root, and a third ſort both by the ſeed and root.

Weeds may be divided in the ſame manner, into annuals and perennials. But, in treating of the methods of deſtroying them, we will be better underſtood, if they are divided into theſe two ſorts; weeds that are propagated by the ſeed, and weeds that are propagated by the root. It is needleſs to conſider the weeds that are propagated both by the ſeed and the root, as a third ſort. For when their ſeeds infeſt the land, they muſt be treated as weeds that are propagated by the ſeed; and, when their roots infeſt the land, they muſt be treated as weeds that are propagated by the root. It is neceſſary, however, to divide weeds into theſe two ſorts, into which we have divided them: for, in ſome caſes, that kind of management proper for diſcouraging the one ſort, tends to encourage the growth of the other.

But, beſides theſe two ſorts of weeds mentioned, it will not be improper that we likewiſe take notice of thoſe ſhrubs by which ſome land is greatly infeſted. Theſe, though they are not commonly reckoned in the claſs of weeds, and though ſome of them may have their particular uſes; yet, as they are plants different from what the farmer deſires to cultivate in his fields, they fall under the definition which we have given of weeds, and ſhall be reckoned by us a third claſs.

Methods of deſtroying weeds.

The deſtroying of weeds is certainly one of the moſt important parts of agriculture. By allowing them to grow, we allow the land, as was formerly obſerved, to be robbed of its vegetable food, and its vegetable paſture to be greatly leſſened.

It may be inquired, what becomes of this vegetable food of which they rob the land? It is either conveyed to the air, and ſent to enrich other land, or it is turned into a form that renders it deſtructive.

When weeds wither and putrefy above ground, the ſalts and oils which they contain, and of which they deprived the land on which they grew, become volatile, and fly off into the air, and leave little more than their earth remaining.

When weeds carry ſeed, and ſhed it upon the land, and when the roots, by the nouriſhment they receive, are enlarged and extended; the vegetable food, of which they have deprived the land, is turned into a form that renders it deſtructive, into ſeeds and roots, by which the land is further exhauſted.

The ſeeds and roots of weeds, though deſtructive to uſeful plants, by robbing them of their food, yet they contain vegetable food in themſelves; and, when the ſeeds are picked up by birds, and the roots eaten by animals, the vegetable food is carried off. But, if theſe weeds are deſtroyed, and reduced to a ſtate of corruption, the vegetable food, which they have taken from the land, and rendered deſtructive, is reſtored to it, and becomes beneficial: ſo that land that is poor, and unfit for carrying crops of uſeful plants, by being full of weeds, may be made rich and fertile, by deſtroying them.

From theſe things it appears, that the deſtroying of weeds is one of the moſt important parts of agriculture. As it is important, ſo likewiſe it is difficult.

There is ſcarcely a field, in which we will not obſerve weeds of the two firſt kinds mentioned; of the kind that is propagated by the ſeed, and the kind that is propagated by the root. Some of theſe, perhaps, it may be eaſy to deſtroy, as they are foreigners, and not adapted to the ſoil;

but others of them being natural to the ſoil, in that kind of it that is moſt proper for them, it may be expected, not only that it will be very difficult to deſtroy them, but alſo, that, by the culture given to the land, they will thrive wonderfully, carry great crops of ſeed, and multiply, and extend their roots. As the deſtruction of weeds is then ſo important and difficult, it is a work that muſt be particularly attended to.

Weeds have been divided into three ſorts. To deſtroy theſe different ſorts, different management is required. It is neceſſary therefore to treat of them ſeparately.

Methods of deſtroying weeds that are propagated by the ſeed.

Weeds are very different in their natures. The ſeeds of ſome of them will putrefy in a few years, if they lie moiſt in the earth, and are prevented from vegetating. But the ſeeds of others will lie many years in this ſituation, without having their vegetative power deſtroyed. This we know from experience. Land infeſted with different kinds of weeds, has been frequently thrown out into graſs, and allowed to remain in that ſituation for ſome years. Though allowed to lie only a few years, ſome kinds of weeds are found to be deſtroyed, when the land is broke up again; but, though it lie twenty years, ſome other kinds are found in as great plenty as before.

The firſt ſort may be deſtroyed by turning the land infeſted with them, from tillage into graſs, and allowing it to remain in that ſituation for five or ſix years.

Both ſorts may be deſtroyed by bringing the ſeeds to vegetate, and then tearing up the young plants. Seeds will not vegetate without air. Some require a greater proportion, and ſome a ſmaller. The ſmall ſeeds will not vegetate without a very great proportion of it. It may be obſerved, in fallowing land which is full of weeds, that great numbers of them appear after every ploughing. This ſhows, that ſome of the ſeeds had not a ſufficient quantity of air, in their former ſituation, to make them vegetate. Now, to give theſe ſmall ſeeds the proportion of air neceſſary for them, they muſt be brought near the ſurface, and the earth about them rendered free and open. If the land is frequently ſtirred and turned over, both theſe will be done. For every time the land is ſtirred and turned over, ſome ſeeds, that before lay deep, are brought near the ſurface, and the earth about them alſo rendered free and open: and, beſides, the plants that have appeared are thereby torn up and deſtroyed.

Every farmer that practiſes ſummer-fallowing, is now fully convinced of the truth of this. For he obſerves, when the ſeaſon is favourable, and his fallow is well and frequently ploughed and harrowed, and time allowed betwixt every ploughing and harrowing for the weeds to vegetate, that his land, for ſeveral years, is not ſo much infeſted with weeds as before.

It has been obſerved, that ſeeds will not vegetate without air, and that to give the ſmaller kinds the quantity which they require, they muſt be brought near the ſurface, and the earth around them rendered free and open. It is neceſſary likewiſe to obſerve, that water is as requiſite to promote vegetation as air; and that the bringing ſeeds near the ſurface, and rendering the earth free and open around them, as it ſupplies them with air, tends to deprive them of water. In the performance, therefore, of thoſe operations by which the land is ſtirred and turned over, to promote the vegetation of the ſmall ſeeds, great care muſt be taken to preſerve the ſap, as much as is poſſible. This will be done, if, in ſtirring the land, the ſurface is made ſmooth and plain. It is obvious, that, when the ſurface is rough and uneven, the drought has eaſy acceſs; but, when it is ſmooth and plain, the winds have leſs influence, and the ſap is better preſerved. Every farmer will obſerve, that, in dry weather, when land is allowed to lie ſome time after it has been ploughed, without being harrowed, the drought has eaſy acceſs, the ſap is exhaled, and the ſeeds in it, though near the ſurface, and the earth around them free and open; yet, being deprived of water, are prevented from vegetating: whereas, when the land is harrowed immediately after it is ploughed, the ſap is preſerved, and the ſeeds ſpring up. Hence the cuſtom of ſowing barley immediately after the plough. Barley is commonly ſown in a dry ſeaſon; and therefore the land is not allowed to lie long after it is ploughed, leſt the ſap ſhould be exhaled; but is immediately ſown and harrowed, by which the ſap is preſerved.

The vegetation of ſeeds in land is promoted, not only by ſtirring and turning over the land, but alſo by the application of dung and ſome other manures. Dung raiſes a fermentation; this opens the pores of the ſoil, allows the air to reach the ſeeds, and gives them liberty to put forth their roots. If dung, therefore, is laid upon land infeſted with weeds, and the land carefully ſtirred and turned over ſeveral times, all the ſeeds in it, by degrees, will be brought to vegetate; and thus the weeds will be deſtroyed.

It muſt be owned, that this practice, though proper for deſtroying weeds, may, in ſome caſes, deſtroy ſome of the virtues of the dung, before it is applied to promote the vegetation of the uſeful plants we deſign to cultivate. Dung promotes vegetation, by producing a fermentation in the ſoil upon which it is laid; and, by this fermentation, ſeparating its particles. If this fermentation is, in a great meaſure, over before ſeed is ſown, the natural weight of the ſoil, making it ſubſide, will render the vegetable paſture, while the plants are growing, much leſs than it would have been, if the dung had not been ſo ſoon laid on; and more harm may be done by this, than advantage gained by deſtroying the weeds. But, though it may be improper to follow this method, when ſeed cannot be ſown for a conſiderable time after the dung is laid on, as is the caſe ſometimes when ſummer-barley is ſown on fallow; yet it may anſwer very well, when ſeed is to be ſown ſoon after, as is the caſe when wheat is ſown. The advantages ariſing from the deſtruction of the weeds, though not in the firſt caſe, yet in the laſt, may probably do more than overbalance the loſs ariſing from ſome part of the ſtrength of the dung being exhauſted before ſeed is ſown.

It may, perhaps, be thought a little ſurpriſing, that dung ſhould be propoſed as a means of deſtroying weeds, when it is univerſally conſidered as a great encourager of them. It is certain, that the laying dung upon land makes more weeds appear, than otherwiſe would do. If the ſeeds of theſe weeds are in the dung, it muſt be owned, that it increaſes, and not diminiſhes their number. But, if the ſeeds are in the land, and the dung only makes them vegetate, it becomes a proper means of deſtroying them.

It ſeems to be the general opinion, that the great plenty of weeds that appear on land after it is dunged, are produced from ſeeds mixed with the dung. But there are ſome reaſons to believe that this is a miſtake.

It is obſerved, that dung produces weeds, when it is taken from a dung-hill, ſo much heated as to deſtroy the vegetative power of any ſeed.

It is obſerved likewiſe, that the ſame dung produces weeds, according to the nature of the land on which it is laid. It often happens, that dung carried from a town is laid upon different ſoils; and it is certain, that this dung does not produce the ſame kind of weeds on all ſoils, which it would do, if the weeds aroſe from ſeeds, mixed with it: but always produces the weeds, with which the ſoil upon which it is laid is naturally infeſted.

Theſe obſervations make it very probable, that the great quantity of weeds produced by dung, is entirely owing to the fermentation occaſioned by the dung; by which almoſt all the ſeeds near the ſurface, receiving a proper quantity of air, are thereby brought to vegetate.

To this it may be objected, That ſuch numbers of weeds do not appear upon land that is new marled, as upon land that is dunged. But, in anſwer to this, let it be obſerved, that a great quantity of marle is laid on, and in large pieces, and that it is ploughed in with a ſhallow furrow: and therefore, though a fermentation may be raiſed, yet the undiſſolved marle prevents a great part of the ſoil from being expoſed to the air, in ſuch a manner as to make the ſeeds in it vegetate; and alſo occaſions ſuch a hollowneſs, that, after the ſeeds begin to vegetate, ſuch of the plants as are tender (and ſeveral ſorts of them are not ſo hardy as corn) are eaſily deſtroyed by drought or froſt.

Before we leave this article, it is neceſſary to obſerve, that the ſeeds of ſome weeds, particularly the different ſpecies of the thiſtle, are carried to a conſiderable diſtance by the wind; and where any earth is thrown up in ſuch a manner as to intangle them, as at the root of a hedge, or ſide of a ditch, there they appear in great plenty. It is ſurpriſing, that many farmers allow them to grow there undiſturbed: the conſequence of which is, that their ſeeds are carried in great plenty into the adjacent fields, and thereby great damage is done; which might have been prevented by cutting them down, at a ſmall expence, before their ſeeds were ripened.

Methods of deſtroying weeds that are propagated by the root.

There are many different kinds of weeds propagated by the root, and theſe of very different natures. Some of them infeſt the land that is in tillage, and others the land that is in graſs. Any perſon may ſatisfy himſelf of this, by inſpecting our fields. The farmer is very ſenſible of it: he knows that ſome kinds of weeds flouriſh and increaſe in his land, while in tillage, if he does not take all pains to diſcourage them; and when he lays down his land in graſs, other kinds that did not appear before, ſoon diſcover themſelves; and, if undiſturbed, continue to increaſe, while the land remains in that ſituation.

The firſt ſort, it ſeems, have ſuch a tender blade, and ſuch tender roots, that they cannot pierce earth that is hard; but are of a kind that increaſe very faſt, when the ſoil is free and open.

The ſecond ſort have the blade and roots ſo ſtrong, that there is ſcarcely any ſoil that, of itſelf, will become ſo hard and ſtiff, as to prevent them from making their way through it; but are of ſuch a nature, as to be eaſily torn up, when the land is free and open; and do not eaſily ſtrike root again when torn up.

The natures of theſe weeds point out methods of deſtroying them.

The firſt ſort, as they chiefly infeſt land in tillage, may be deſtroyed by turning the land from tillage into graſs, and allowing it to remain for ſome years in that ſituation. This is confirmed by experience. Land over-run with quickening-graſs, and other root-weeds of the ſame kind, is frequently laid down in graſs, and allowed to continue for ſome years without being ploughed. This land, when broke up again, if allowed to lie in graſs for ſix or ſeven years, is found to be clean, and the roots of the weeds deſtroyed.

The number of years neceſſary for deſtroying the roots, depends upon the nature of the ſoil. If the ſoil is naturally hard and ſtiff, it is the ſooner brought to ſuch a ſituation, as to prevent the roots and blades of the weeds from piercing it. But, if it is naturally ſoft and ſpungy, it takes a longer time before it is brought to that ſituation. For while the blade, or roots of the weed, can pierce the ſoil, their vegetation is not prevented. In ſome ſoils, it is ſix or ſeven years before the roots of the quickening-graſs are deſtroyed.

The number of years found neceſſary for deſtroying theſe root-weeds, has, no doubt, been partly the occaſion of eſtabliſhing the practice commonly obſerved. Three crops of corn are taken, and then the land is allowed to lie ſix years in graſs, or lea. At the end of theſe, the farmer ſuppoſes that the lea is come to maturity, and fit again for being ploughed. When it is only two or three years old, it is called, in ſome parts of the country, calf-lea; and, if ploughed at that age, is commonly very full of roots.

The ſowing land with graſs-ſeeds, inſtead of turning it out into lea, deſtroys the roots of theſe weeds ſome years ſooner. For thereby a ſward being brought immediately upon the ſurface, the land becomes firm, the blades of the weeds are unable to pierce it, and the roots are deprived of air. Ryegraſs-ſeed, or the common hay-ſeed, is the moſt proper for this. For the plants ariſing from theſe, ſoon cover the ſurface, and, by the number and ſmallneſs of their roots, bind the ſoil. Clover, particularly the broad clover, is improper. For the roots of it being large, they open the ſoil in growing and extending themſelves, and thereby prevent it from arriving at that degree of firmneſs, neceſſary for deſtroying the weeds ſo ſoon, as if no graſs-ſeeds are ſown, but the land immediately turned into lea.

The ſecond ſort may be deſtroyed by turning the land infeſted with them, from graſs into tillage; and it is not neceſſary to continue it long in this ſituation, for the weeds commonly diſappear after the firſt ploughing.

But as it may be inconvenient to turn a field infeſted with weeds, from graſs into tillage, or from tillage into graſs; it is neceſſary to conſider, if there are any methods of deſtroying theſe weeds, without altering the ſituation of the land.

When land in tillage is infeſted with weeds, they may be deſtroyed by frequently ſtirring and turning it over in dry weather. For the weeds being removed out of their place, the drought prevents them from ſtriking root again. The ſtirring the land in wet weather, is rather hurtful than beneficial. For though the roots of the weeds are removed from their place, yet the weeds themſelves are only tranſplanted. If the land is wet, they ſoon ſtrike root again; and the quickening-graſs, in particular, having its paſture enlarged, makes quicker progreſs than ever.

ever. But, if the land is dry, the weeds do not ſo eaſily ſtrike root again: or, if ſome of them ſhould ſtrike root, they continue for ſome time in a languiſhing condition, and if removed out of their place, while in this condition, are eaſily deſtroyed by the drought. If land then is frequently ſtirred and turned over, by degrees all the weeds will be deſtroyed: for, by every ſtirring or ploughing, ſuch of them as are in a languiſhing condition are deſtroyed, while thoſe that are ſtrong and vigorous are weakened.

When land is to be freed from ſeed-weeds, it cannot be made too fine, nor the ſurface too ſmooth; for the more perfectly theſe are done, the greater number of ſeeds are brought to vegetate. But, when land is to be freed from root-weeds, it cannot be turned up in too large pieces, nor the ſurface left too rough: for the larger the pieces, and the rougher the ſurface, the drought has the eaſier acceſs, and the roots are the more effectually deſtroyed.

When land in graſs is infeſted with weeds, and it is inconvenient to turn it into tillage, the weeds themſelves muſt be pulled up by the root, or frequently cut; which are the only ways of deſtroying them.

Some perſons aſſert, that ſheep are very fond of the yellow rag-weed, by which light land, when laid out in graſs, is very much infeſted. If this is true, the putting ſheep to paſture upon this graſs, for a ſeaſon or two, will effectually deſtroy this weed. This may be the more ſafely recommended, as the trial, though it does not ſucceed, cannot be attended with any danger or loſs.

Some land, after being a few years in graſs, is liable to be over-run with fog. This, it is ſuppoſed, is owing to the ſoil becoming ſoft and ſpungy near the ſurface. If this is the caſe, rolling, which makes the ſurface firm, will be of ſome uſe to deſtroy this pernicious weed. It may be obſerved, that, when there is a foot-path through a graſs-field over-run with fog, not ſo much frequented as to break the turf, the graſs upon the path is clean, without any mixture of fog.

There is a third ſort of weeds found to infeſt both the land that is in tillage, and the land that is in graſs. This ſort have not only the blade and roots very ſtrong, ſo as to be able to pierce the ſoil, though hard, but alſo are of ſuch a nature, as makes it difficult to tear them up; or have their roots of ſuch a kind, that they may be divided into a great number of plants.

Theſe weeds cannot be deſtroyed, either by turning the land infeſted with them, from tillage into graſs, or from graſs into tillage: but they may be deſtroyed by the methods mentioned, when the ſituation of the land is not changed. If the land is in graſs, they may be deſtroyed by digging them out, or by frequently cutting them. And, if the land is in tillage, they may be deſtroyed by frequently ſtirring and turning it over in dry weather. This work muſt be performed with ploughs properly made for cutting their roots. This kind of weeds puſh their roots very far down, and their roots are ſo tough and hard, that our common ploughs ſeldom break them. If there are any ſtones in the land, they puſh their roots among the ſtones; and, in ſuch places, the plough not having freedom to act, they continue undiſturbed. In this land too the plough moſt proper for cutting theſe roots, cannot go with ſafety. But if the ſtones are dug out, and the land ploughed with a broad pointed ſhare, the roots, by degrees, will be cut, and the weeds deſtroyed.

Beſides theſe three ſorts of weeds mentioned, there is a fourth that chiefly infeſts land that is wet. Frequent cutting, and even digging out by the root, have been tried to deſtroy them, but to no purpoſe. They are not to be ſeen on dry land, and, when on land only inclining to be wet, appear very weak. This points out draining to be the proper method of deſtroying them, which indeed does it effectually.

We ſhall now conclude this article with obſerving, that all kinds of root-weeds, and many kinds of the ſeeds of weeds, may be deſtroyed by depriving them of air. For air is neceſſary not only to the vegetation, but alſo to the life of every plant.

When land is in tillage, the weeds may be deprived of air, either by burying them deep in the earth, or covering the ſurface. Trenching does the one, and a good crop of peas, potatoes, or any other plants that lie thick on the ſurface, does the other.

Fog, by which ſome lands in graſs are much infeſted, may be deſtroyed in the ſame manner. The method propoſed is this: the graſs muſt be kept from the month of March to the month of December, for winter-paſturing, and the next ſeaſon preſerved for a crop of hay. The fog being, by this management, covered for two ſeaſons by the graſs, is thereby deſtroyed.

As different methods are neceſſary in the extirpation of different weeds, and it is of ſome importance to know which of them are perennial, and which only annual, we have added a liſt of the moſt remarkable weeds which infeſt the arable and graſs lands in England, ranged according to their duration. A pomp of names is carefully avoided, and thoſe which Mr. Hudſon has given in his Flora Anglica are choſen: it is a misfortune that many farmers will not know what plants are meant by ſome of theſe names; but it is a misfortune ſcarcely to be avoided, ſince the Engliſh names of vulgar plants are ſo various; altering not only with the county, but with the place, and even ſometimes depending on the whim of a common labourer.

By far the greater number of annual weeds infeſt the arable lands: in graſs lands the perennials chiefly flouriſh. The reaſon is obvious; in the former the roots are continually deſtroyed by cutting; in the latter they are made to ſpread by cutting or eating down the ſtems: perennials uſually require more than a year to come to perfection; and the ſeeds by which annuals are propagated, are not ſo readily received into the more compact turf, as into land whoſe parts are conſtantly undergoing a ſeparation.

The annual weeds which infeſt arable lands and gardens are chiefly theſe,

Ivy-leaved ſpeedwell, or ſmall henbit. April.
Annual darnel-graſs.
Bearded oat-graſs, bearded wild oats, or haver.
Little-field madder. May.
Cleavers, or gooſe-graſs. May.
Parſley-piert. May.
Pearl-wort, or chickweed breakſtone. This ſmall weed is very apt to infeſt gravel-walks; and if it be ſuffered to ſeed, will increaſe prodigiouſly, and grow very troubleſome. June.
Baſtard alkanet. May.
Small wild bugloſs. June.
Male pimpernel. May.
Venus's looking-glaſs, or codded corn-violet. June.

Dodder,

Dodder, hell-weed, devil's-guts, or ſcald. July.

This is found chiefly on beans; it ſtrangles the crop, and draws its nouriſhment from the plants about which it entwines itſelf. It infeſts alſo hops and flax.

Small corn-parſley. Auguſt.

Gooſefoot of ſeveral kinds flouriſhes on dunghills, and is often ſuffered by the farmers to grow there unmoleſted, by which the dung is much exhauſted. Auguſt.

Fool's parſley. This is generally allowed to be a ſtrong poiſon, and is very common in gardens.

Shepherd's needle, or Venus's comb. June.

Common chickweed. The peſt of gardens.

Knot-graſs. This plant is remarkably full of ſeed, and propagates itſelf ſurpriſingly: it will grow any where, particularly in places that are much trodden. The ſparrows, and other ſmall birds, are very fond of its ſeeds. June.

Black bindweed. June.

German knot-graſs, or annual knawel. Auguſt.

Purple-flowered chickweed, or ſpurrey; on ſandy lands. June.

Cockle. June.

Corn ſpurrey. Auguſt.

Petty-ſpurge. July.

Sun-ſpurge, or wart-wort. Theſe are both very common in gardens. July.

Red-poppy, or corn-poppy. June.

Wild larkſpur. This has increaſed ſo much of late years in Cambridgeſhire, as to become one of the common weeds among the corn.

Adonis flower, pheaſant's eye, red maithes, red Morocco. Frequent in the corn-fields of Kent.

Corn crowfoot. The ſeeds of this do not come forth till the ſecond year after ſowing. June.

Upright ground-ivy.

Red archangel, or dead-nettle. Common in gardens.

Great henbit.

Narrow-leaved all-heal.

Nettle-hemp, or hemp-leaved dead-nettle.

Red eye-bright.

Fluellin; ſharp-pointed, and round-pointed.

Gold of pleaſure; among the flax. June.

Shepherd's purſe.

White-flowered charlock, with a jointed cod. June.

Yellow-flowered ditto.

Wild muſtard, or charlock. May.

Theſe three, particularly the laſt, are the *opprobium* of the farmers: they who will not be at the pains to extirpate them by hand, might do well at leaſt to run a ſcythe over the crops, while the weed is in flower, and before their ſpring-corn (for it is that which is chiefly troubled with it) is got up too high.

Fumitory. April.

Yellow vetchling; very common in the corn-fields about Cambridge.

Common ſow-thiſtle. June.

Common groundſel.

Corn-marigold; the peſt of light lands: it is not fond of dung. In Denmark there are laws for the extirpation of this weed. June.

Common camomile, or corn-feverfew. June.

Stinking May-weed. June; ſomewhat earlier than the laſt.

Blue-bottles. July.

Panſies, or heart's-eaſe.

Leſſer nettle. Auguſt.

Oracee, of ſeveral kinds; along with the gooſefoot, on dunghills, and in gardens. Auguſt.

Annual weeds in paſture-grounds are only the following.

Purging-flax. May.

Knot-graſs. This ſpreads chiefly by the path ſides, and where dung or rubbiſh has lain.

Yellow rattle, or cock's-comb, vulgarly penny-graſs; in moiſt meadows. This keeps its ground, for the ſeeds are ripe at the time of cutting hay. June.

Eye-bright; in dry paſtures.

Red eye-bright.

Heart-trefoil, or clover. This is always mixed with clover, and particularly with the hop-trefoil, or non-ſuch. It is a harſher plant, full of hard, prickly ſeed-veſſels, and therefore not a good food for cattle: it is eaſily known from other clovers, by its ſeed-veſſels, and the ſpots upon its leaves.

Common creeping mouſe-ear. May.

Smooth ſuccory hawk-weed. June.

Star-thiſtle; in dry barren paſtures, and by way-ſides. July.

Hairy ſheep's ſcabious; on high paſture.

Biennial weeds in corn.

Viper's bugloſs, called in Cambridgeſhire, &c. cat's tail. It infeſts the corn very much every third year. July.

Mithridate-muſtard, or baſtard-creſs.

Common melilot. The ſeeds of this ground along with wheat, are known to give bread a very ſtrong taſte. June.

Spear-thiſtle. July. This, with many other kinds of thiſtles and other weeds, with downy ſeeds, are ſuffered to ſtand on banks, way-ſides, and fallow lands, in order to ſerve for a conſtant ſupply of weeds. If the waſte places were run over with an old ſcythe, this evil would ſoon be prevented.

Biennial weeds in paſtures.

Wild-carrot, or bird's neſt. June.

Cow-parſnep. July.

Common-mallow. May.

Rough-ſuccory hawk-weed. July.

Stinking hawk-weed. June.

Muſk-thiſtle. July.

Wild carline-thiſtle. June.

Perennial weeds in corn.

Field fox-tail, or mouſe-tail-graſs.

Common wheat-graſs, dog's-graſs, quick-graſs, or couch-graſs. As every piece of this moſt deteſtable creeping weed will grow, there is no way of deſtroying it, but by ploughing up the ground thoroughly, picking it out, and burning it.

Common field-ſcabious. Auguſt.

Small bind-weed. This ſpreads its roots deep and wide; and as every piece of them will grow, it is no eaſy matter to eradicate this pernicious plant.

Bladder-

Bladder-campion, white corn-campion, ſpattling-poppy. July.

White-campion. May.

Small-bramble, or dewberry-buſh. June.

Corn-mint. Auguſt.

White-archangel, or dead-nettle; chiefly in gardens and under hedges.

Corn reſt-harrow, or cammock. The roots of this mat together with great ſtrength, and are therefore very troubleſome, where land is to be ploughed for corn. This property, however, makes it an excellent plant to ſet on ſea and fen banks, to keep them firm and compact. July.

Free ſow-thiſtle. Auguſt.

Way-thiſtle. The fallows are uſually well overſpread with this weed, whoſe downy ſeeds are eaſily ſpread by the wind. July.

Great knap-weed, or matſellon. Its roots are very ſtubborn and hard. July.

Corn horſe-tail.

Perennial weeds in paſtures.

Devil's-bit. June.

Great-plantain, or waybread. June.

Ribwort, or ribwort-plantain. June.

Yellow ladies bed-ſtraw, or cheeſe-renning. It is a vulgar notion, but a falſe one, that this herb will turn milk. The good women are fond of putting ſome favourite plant into their rennet, and thus attribute to it a quality which it has no right to claim. July.

Cowſlips, or pagils. April.

Round-leaved bell-flower. Auguſt.

Leſſer throat-wort, or Canterbury-bells. July.

Meadow-ſaxifrage. Auguſt.

Burnet-ſaxifrage. Auguſt.

Crow-garlic. This gives milk and butter an inſufferable ſtrong taſte. June.

Broad-leaved dock. July.

Common-ſorrel. May.

Sheep's ſorrel.

White ſaxifrage, or ſengreen. May.

Agrimony. June.

Drop-wort. Hogs are fond of the roots. July.

Meadow-ſweet. June. Only in very moiſt meadows. Goats are very greedy of this plant, which neither horſes nor kine will touch.

Tormentil, or ſeptfoil. June.

Creeping-crowfoot, or butter-cups. May.

Bulboſe-crowfoot, or butter-cups. May.

Upright meadow-crowfoot. June.

The three laſt, which occupy ſo much room in almoſt all meadows, are not eaten by any ſort of cattle, being of a very hot and acrid nature, ſo that the notion of their giving butter a yellow tincture, is as falſe as it is vulgar.

Pilewort, or leſſer celandine. April.

Meadow-rue. June.

Bugle. May.

Self-heal. Auguſt.

Common yellow toad-flax. July.

Common ladies-ſmock, or cuckow-flower. April.

Crowfoot craneſbill. June.

Common broom: in dry paſtures. May.

Reſt-harrow, or cammock; in barren grounds.

Dandelion. April.

Rough dandelion. May.

Yellow devil's bit. Auguſt.

Long-rooted hawk-weed. May.

Dwarf carline-thiſtle. July.

Common coltsfoot; in watery days. March.

Common butter-bur; in moiſt meadows. March.

Ragwort, or ſeagrim. Nothing touches this plant; though a perennial, it comes up eaſily by hand, when young, or when the ground is moiſt. July.

Fleabane; in moiſt places. Auguſt.

Common daiſie. We do not find that any cattle willingly eat of this plant, which occupies ſo large a part of our paſtures.

Greater daiſie, or ox-eye. May.

Common yarrow, or milfoil. The roots of this creep abominably, eſpecially where rubbiſh, or dung has been laid. May.

Common knap-weed, or matſellon. July.

Orchiſes of various ſorts; as,

Butterfly orchis. May.	In moiſt meadows.
Male fool-ſtones. May.	
Female fool-ſtones. May.	
Male-handed orchis. May.	
Female-handed orchis. June.	
Red-handed orchis. June.	
Purple late-flowering orchis. June.	In dry paſtures, chiefly in chalk.
Little purple-flowered orchis. May.	
Man orchis. June.	
Frog ſatyrion. May.	
Triple ladies traces. Auguſt.	
Bee orchis. June.	

Carexes of various ſorts; in low meadows and fenny grounds. Theſe are all very harſh: they are, however, mowed to fodder cows with in winter.

Common nettle.

Adder's tongue; in moiſt meadows.

Female fern, or brakes; on dry barren land. It ſtrikes its roots far and wide, and is difficult to eradicate even with the plough.

Moſſes of various ſorts. Old paſtures are moſt infeſted with theſe. Ploughing is the only effectual way of deſtroying them.

We have added the time in which moſt of the foregoing plants begin to flower; becauſe about that time it is proper they ſhould be deſtroyed.

Though the reader will find an account of many of the weeds enumerated in the above catalogue, under their proper articles, yet we were perſuaded that a general deſcription of the perennial weeds would not be unacceptable here, as too much cannot be ſaid to enable the huſbandman to know theſe pernicious plants, and exterminate them as ſoon as poſſible.

Annual darnel-graſs is called white darnel by Gerard, and in the ſouthern counties crap; though, in Worceſterſhire, they call the buck-wheat by this name. It was a ridiculous old notion, that this weed, which has ever been ſtigmatized as one of the greateſt peſts of corn, is produced from bad ſeed of wheat. The French call it *yvroie*; becauſe, put into bread, or beer, it is ſuppoſed to cauſe drunkenneſs. It has always been reckoned bad for the eyes, and to occaſion vertigoes. This plant is very like the red darnel-graſs, which has been ſo much cultivated, under the name of ray-graſs, or vulgarly rie-graſs: but the ſpike is much larger and paler; and has beards, which the ray-graſs is entirely without. It is likewiſe annual:

whereas the ray-graſs has an abiding root. Its ſeeds ripen with the corn.

Bearded oat-graſs, or wild oats, is very like the common oat in appearance, but generally over-tops it. The ſeeds are alſo of a duſky reddiſh colour, and hairy towards the bottom. The beards or awns are very long, ſtiff, and bent. As it ripens with the corn, or but little before it, the extirpation of it is not very eaſy.

Baſtard alkanet is called, alſo, baſtard gromill, or gromwell, and ſalfern. Nothing is more common among the corn, eſpecially among rye, than this weed. It may eaſily be known, by its red roots, which yield a red tincture, and are uſed by the country girls in Sweden, to ſmear their faces with. From the root uſually riſes a ſingle ſtem, about a foot high, rough, and branching out at the top. The flowers are ſmall and white, ſurrounded with five long, narrow, hairy leaves, and ſucceeded by four white rough ſeeds.

The dodder is ſo remarkable a plant, that it cannot be miſtaken by thoſe who know the name. It is entirely without leaves, and does not depend on the ground for nouriſhment; but when it is grown up, rots at the bottom, and lives upon the juices of other plants, about which it entwines itſelf, by means of ſmall threads of a red colour, which it throws out. The flowers are ſmall, and come out in roundiſh heads, or bunches, many of them together, here and there, from the ſtem.

Small corn parſley, though it is very common among corn, does not ſeem to be much known. It is a low branching plant. The branches grow thick together, and are knotted and crooked. The flowers grow thick together after the manner of parſley, &c. and are of a white colour inclining to yellow. The ſeeds are large in proportion to the plant, and are ſet about with little crooked briſtles, which make them adhere to the ſtockings in great plenty, when the ſeeds are ripe, which is about, or a little after harveſt.

The leſſer hemlock, called by Gerard, thin-leafed wild hemlock, is ſo well known under the name of fools parſley, as ſcarce to need a deſcription. However, as it is a matter of conſequence to diſtinguiſh poiſonous plants from thoſe which they reſemble, we may obſerve, that though the leaves reſemble parſley, yet they are much darker on their upper ſurface, but pale and ſhining underneath. The diviſions of the leaves are much ſharper, and they have no ſmell, nor ſcarcely any taſte. When the plant is in flower, it is eaſily known by the three long narrow green leaves, which hang down from the little ſtems that immediately ſupport the flowers.

Shepherd's needle, or Venus's comb, has its names from the remarkable ſhape of the ſeeds with their appendage, reſembling in this reſpect the cranes bills: theſe would be alone ſufficient to diſtinguiſh the plant. They ſucceed ſmall white flowers; and come out in a bunch, like needles, or the teeth of a comb, ſet cloſe together. The leaves are very finely cut.

Knot-graſs is ſo called from its knots or joints, of which its ſlender creeping branches are full. After harveſt, the lands, in many places, ſeem all coloured with the little red flowers of this plant. It is called, alſo, ſwine's-graſs; and, in the north, bird's tongue.

Black bindweed has a ſtem that lays hold on any neighbouring plants, and twines about them from right to left. Its leaves are ſmooth, and ſhaped pretty much like thoſe of the buck-wheat, which its ſeeds alſo reſemble, being triangular, but ſmaller. It frequently ramps up in hedges and gardens, and is alſo very common among corn.

Corn-crowfoot has an upright ſtalk. The leaves are of a pale green, and cut into long, narrow, acute ſegments. The flowers are much ſmaller, and paler than in the crowfoots of the paſtures; but the ſeed-veſſels are the moſt remarkable, for they are covered all over with prickles. This is extremely common among corn.

Charlock, called, alſo, chadlock, catlock, carlock, and wild rape, is, I ſuppoſe, too generally known to need a deſcription. The white and the yellow-flowered charlock, or wild radiſh, which are the only varieties of each other, and not ſo common as the former, may eaſily be diſtinguiſhed from it, by the paleneſs of their flowers, and the form of their ſeed-veſſel, which is round, ſmooth, and jointed. Almoſt the whole plant is covered with bent pellucid hairs.

Yellow vetchling, or ſmall yellow fetch, has long, ſlender, divided ſtalks. The leaves are triangular, and grow by pairs cloſe to the ſtalk. Out of theſe leaves comes a tendril, by which the plant ſupports itſelf; and, on a long ſtalk, one ſmall pea flower, of a yellow colour, which is ſucceeded by a flat pod, about an inch in length, containing ſix or ſeven roundiſh ſeeds.

Corn-marigold, or golden corn-flower, is the buddle, or yellow buddle of Kent. Its leaves grow cloſe to the ſtem, in an alternate order. They are of a blue-green colour, and are cut about the edges. The flowers are like thoſe of the marigold; large, and of a beautiful yellow.

Yellow rattle is known by its leaves being finely indented about the edges, its flowers being yellow; and its ſeed-veſſel ſwelling into a dry, large, compreſſed bladder, divided into two cells, and containing ſeveral compreſſed ſeeds, ſurrounded with a membrane.

Red eye-bright, or eye-bright cow-wheat, has a ſtem riſing not more than a foot high; long narrow leaves, indented about the edges, and purple flowers growing in ſpikes. It flowers in July and Auguſt.

Viper's bugloſs. The ſtalks are rough, round, ſolid, erect, undivided, and marked with black ſpots; the leaves are very rough, long, narrowing to a point, and placed without any certain order. The large ſpecious flowers, of a beautiful blue colour, grow in long bending ſpikes. They conſiſt of one petal, divided into five roundiſh ſegments, of different ſizes, and reſemble a horn in their figure, expanding by degrees, from a narrow beginning. The flower-cup conſiſts of five narrow ſegments, and contains four rough ſeeds.

Melilot is well known by its trefoil leaves, which are indented, and, as it were, eaten about the edges; and by its long, thin ſpikes of ſmall, yellow flowers, which are ſucceeded by ſhort rough pods, containing two ſeeds.

Wild carrot, bird's-neſt, or bee's-neſt, is very like the cultivated carrot, of which it is indeed ſuppoſed to be only a variety. The wild ſort, however, differs in its roots being ſmall and ſticky. In both ſorts, after they have done flowering, the umbels contract themſelves into the ſhape of a bird's neſt.

Cow parſnep, wild parſnep, meadow parſnep, or madnep. This grows three feet high. The ſtalk is round, furrowed, and hollow. The leaves proceed from a large membrane, or ſheath. They grow on long hairy ſtalks, and are divided and downy. The flowers grow in large umbels, are white, and conſiſt of five irregular petals.

Two oval, ſtreaked, compreſſed ſeeds, ſurrounded by a wing, ſucceed each flower.

Stinking hawkweed may be diſcovered by its very ſtrong ſmell like caſtor. As it is not a common weed, it is not neceſſary to be particular in the deſcription of it.

Muſk-thiſtle is known by its handſome purple nodding heads of flowers, which come out rather ſooner than moſt ſorts of thiſtle. The ſmell of them is agreeable.

Carline-thiſtle is very different from the other thiſtles. The hard, woody root, ſends up one round purpliſh ſtalk, beſet with prickly leaves in no order. This is terminated with ſeveral flowers, growing in a head. The ſmall ones, compoſing the whole, are of a duſky purple, and contained in a ſwelling ſcaly cup; the inner ſcales of which are very long, ſhining, coloured, ſpreading, and placed in a ring round the flowers. The ſtalks and heads remain all the year, with very little variation, upon the dry paſtures.

Perennial weeds in corn.

Field fox-tail, ſmall baſtard fox-tail, or mouſe-tail graſs, is known by its long, round, ſlender, ſmooth ſpike, of a duſky purple colour. The ſpikes are ſo very long and ſlender, that they uſually bend a little. This graſs is found in the moiſt furrows of arable land, and in any places where the water is ſuffered to ſtand.

Common wheat-graſs, or couch-graſs, is univerſally known, by its long white creeping roots. It grows very tall, eſpecially in hedges. The ſpike reſembles that of wheat, in the manner in which the ſeeds are diſpoſed.

Common field ſcabious is all over rough and hairy. The ſtalk is upright; a foot, or a foot and a half in height, ſpotted, and branching. The lower leaves are oval, and indented about the edge. Thoſe which grow on the ſtalk are divided, and of that ſort which botaniſts call pinnatifid. The flowers are blue, of the compound kind; conſiſting of a conſiderable number of ſmall flowers, each divided into four parts, and having one ſeed under them.

The taſte of the plant is a diſagreeable bitter.

Small bindweed, called, alſo, with-wind and hedge-bells, though theſe names ſhould ſeem rather to belong to the great bindweed, which ramps in the hedges; whereas this overſpreads the arable lands. The common people, in their wrath, have given this pernicious weed the ſame opprobrious names with the dodder, viz. hell-weed, and devil's guts.

The ſtalks of this plant are weak, and twine about any thing. They come near, from left to right; and, when they find no ſupport, they trail along the ground. The leaves come out ſingle. They are three cornered, ſhaped ſomewhat like an arrow head, ſmooth, and placed on long foot-ſtalks. From the boſoms of the leaves comes out one flower on a very long foot-ſtalk. It is bell-ſhaped, of a beautiful colour, purple, red, white, or variegated; and is ſucceeded by a ſmall, roundiſh ſeed veſſel, containing four large, angular ſeeds. The whole plant is full of a milky juice.

Bladder-campion, white-corn campion, ſpattling poppy, white bottle, white ben, or frothy poppy. The ſtalks grow a foot and a half, or two feet high, round, ſmooth, jointed, branched towards the top; and at every joint is a pair of leaves, perfectly ſmooth. The flowers are white, and conſiſt of five bifid petals. The empalement, or outward covering, is puffed out into a roundiſh form; and is ſmooth, often varied with red, green, and white, and beautifully veined all over, like a fine net.

White campion, admitted into gardens, when it has a double flower, under the name of white batchelor's-buttons. It has a long and large root, of a ſharp bitteriſh taſte, ſending forth ſeveral ſtalks about two feet high; round, hairy, jointed, branching, of a red colour near the ground; a pair of leaves comes out at every joint, hairy, and ſharp-pointed. The flowers are like thoſe of the laſt: but the empalement, which is not puffed out like that, is oblong, with purpliſh ſtreaks down along it from top to bottom. The flowers of this are imperfect: the male or barren, and the female or fruitful, growing on diſtinct plants.

Small bramble, or dewberry-buſh, is diſtinguiſhed from the common bramble of the hedges, by the place of its growth, the trailing of its round branches, the ſmallneſs of its prickles, which are fewer in number, and chiefly on the ſtalks; the leaves growing only three together, being green underneath, and the ſide ones divided into two parts; and the blueneſs of its berries, which conſiſt of a very few large diviſions.

Corn-mint. We are told, on undoubted authority, that this herb will hinder milk from curdling; and that, when hungry cows have been put after harveſt into a field where this plant abounded, it has been ſcarcely poſſible to turn their milk for cheeſe.

Corn reſt-harrow, reſt-plough, cammock, pretty whin, or ground furze. The hard, ſtubborn, creeping roots ſend forth many woody, round, ſlender, hairy branches, red towards the bottom. The leaves grow three together. The flowers of the pea kind, of a beautiful red colour, and are ſucceeded by a ſwelling, villous pod, containing a few roundiſh ſeeds.

Tree ſowthiſtle. The root is very creeping, full of milk, and with difficulty eradicated. The ſtalk is about two feet high, ſmooth at the bottom, but hairy where it begins to branch out. The leaves are like thoſe of the dandelion, deeply cut, ending in ſharp points, and having the edges ſet round with tender prickles. The flowers grow ſeveral together; and reſemble thoſe of the ſow-thiſtle, but are much larger, of a deeper yellow, and ſurrounded by a very rough, hairy, dark-coloured empalement. They have the ſmell of bitter almonds, and are ſucceeded by downy ſeeds.

Great knapweed, matſellon, or bulweed. This plant is about two feet high. The ſtalks are round, ſtreaked, and hoary. The bottom leaves are oblong and undivided; but thoſe, which grow on the ſtalk, are cut and divided. The flowers reſemble thoſe of the blue-bottle in ſhape, but are of a red colour. The ſeed is ſmall, oblong, reddiſh, and hairy in the upper part.

Corn horſe-tail grows in moiſt places. In April, naked ſtalks come up, which bear the flower and ſeed. Theſe are but of ſhort duration. In May, other ſtalks ariſe, hollow, jointed, about a foot high, and ſending forth all round, hollow jointed leaves, ſix or eight inches in length, ſubdividing into others at the joints.

Perennial weeds in paſtures.

Devil's bit is a kind of ſcabious. It differs from the common field ſcabious, in having undivided leaves, ſet thicker on the ſtalk; in the flowers not ſpreading out into

a flat ſurface, but growing in a round form; and the ſmall flowers, which compoſe the whole, being all of a ſize and regular: and, laſtly, in the root looking, as if it were bit off at the end.

Great plantain, or waybread, is eaſily known by its broad leaves, ſpreading on the ground, and marked on the under ſurface with ſeven ſtrong nerves. From the centre of theſe ariſe ſeveral naked, round, hairy ſtalks, ſuſtaining a long, cylindrical ſpike of ſmall flowers, ſet thick together.

Rib-wort plantain has much longer leaves, marked only with five nerves. The ſtalks are higher, and not round, but cornered, and the ſpikes of flowers are ſhorter.

Yellow ladies bedſtraw, cheeſe renning, maid's hair, petty mugwet. Its ſlender ſtalks riſe to about a foot. The leaves come out in whorls, eight or nine together. They are long and narrow, and of a deep green. Towards the top of the ſtalk, two little branches uſually come out, ſuſtaining a conſiderable number of ſmall yellow flowers, conſiſting of one petal, divided into four parts, and ſucceeded by two ſmooth roundiſh ſeeds.

Round-leaved bell-flower. The bottom leaves are roundiſh: thoſe upon the ſtalk long, and narrow. The flowers are blue, bell-ſhaped, with the edge divided into five parts, and hang down.

Leſſer throatwort, or Canterbury bells. The ſtalk is cornered and undivided, about a foot high, and hairy. The flowers grow at the top of the ſtalk cloſe to it, ſeveral together. They are erect, of a beautiful purple colour, and divided to the middle into five acute ſegments.

Meadow ſaxifrage, Engliſh ſaxifrage, or ſtone-break. The root has a ſharpiſh, aromatic taſte. The ſtalks are round, ſtreaked, and reddiſh towards the bottom. The leaves are ſmooth, of a dark green, and divided twice into long, narrow, ſharp ſegments. The foot-ſtalks membranaceous at the baſe. The flowers grow in looſe umbels, and are of a pale yellow. The ſeeds are oval, ſtreaked, and red at the top.

Burnet ſaxifrage is of two kinds. The large is found in woods; and the ſmaller, in dry paſtures. Of this laſt there is a variety, differing only in the leaves, which are cut even to the root. The ſtalks are ſtreaked, and branched. The flowers grow in umbels cloſe together. They are ſmall, white, and conſiſt of five entire petals. Theſe are ſucceeded by two ſeeds of an oblong oval form. The root has a very hot taſte.

Crow garlick, or wild garlick. The leaves are round and ſmooth, reſembling much thoſe of ruſhes. From the midſt of theſe riſes a ſtalk, a foot or more in heighth, naked, ſlender, round, ſmooth, and hard; ſuſtaining many purple ſeeds, or little bulbs, about the ſize of grains of wheat collected into a round head.

White ſaxifrage, ſengreen, or ſtone-break, has kidney-ſhaped leaves ſpread upon the ground, and divided about the edges, not much unlike thoſe of ground-ivy, but ſofter and ſmaller, and of a faint yellowiſh green. Among theſe riſes a round, hairy, branching ſtalk, about ſix inches high, bearing ſpacious white flowers, conſiſting of five entire petals. This pretty little plant grows in dry paſtures, and may readily be known by its roots, which are made up of little knobs.

From a want of ſufficient diſtinction in names, a ſtrange confuſion has ariſen between the meadow ſaxifrage, Burnet ſaxifrage, Burnet, and white ſaxifrage. It is hoped theſe deſcriptions will contribute ſomething towards avoiding this confuſion for the future.

Agrimony has generally a ſingle, round, rough ſtalk, with leaves placed alternately upon it, which are winged with ſmall leaves, placed between the larger pairs. The yellow flowers grow alternately along the ſtalk, in a long row, after the manner of a ſpike, and are ſucceeded by rough ſeeds.

Dropwort is known by its winged leaves, the diviſions of which are all regular, and ſharply indented about the edges; by its white flowers, growing in a bunch like an umble: but, principally, by its roots, which conſiſt of a bunch of knobs hanging upon threads, from whence it has the names of filipendula, and dropwort. The flowers ſmell agreeably.

Meadow-ſweet, or queen of the meadows. The ſtalk is angular, ſmooth, ſtrong, branching, and of a reddiſh colour. The leaves grow alternately, are winged, and conſiſt of three or four pair of lobes, and a very large one at the end, divided into three parts, like a raſberry-leaf. They are indented about the edges, white underneath, and wrinkled, like the leaf of the elm. The flowers are ſimilar to thoſe of the dropwort. The whole plant has an agreeable ſmell.

Tormentil, or ſeptfoil. The root is large, of a reddiſh colour, and an aſtringent taſte. The ſtalks are weak, and lie on the ground at firſt; but afterwards riſe up. The leaves are hairy, grow cloſe to the ſtalk, and are divided into ſeven parts. The flowers are yellow, and conſiſt of four petals. There is another ſpecies, not ſo common, differing from this only in having its ſtalks lying intirely on the ground, and the leaves growing on foot-ſtalks.

The crowfoots are too common every where to need a deſcription. They are known under the names of king-kob, king-cup, gold-cups, gold-knobs, butter-cups, and butter-flowers. The bulboſe crowfoot is diſtinguiſhed not only by its round root, but by the diviſions of the flower-cups being bent back, the ſtalk being erect, and that which ſuſtains the flowers being furrowed. The upright crowfoot has the diviſions of the empalement ſpreading out, as in the creeping ſort; but the flower-ſtalks are not furrowed, as in that and the bulboſe one. The leaves are divided, firſt, into three parts; and each of thoſe again into ſeveral. The upper leaves are long, narrow, and undivided. This plant grows much taller than the others. The flowers of all three are alike, and of a fine ſhining yellow.

Pilewort, figwort, or leſſer celandine. The root conſiſts of oblong knobs. The leaves are heart-ſhaped, cornered, and placed on foot-ſtalks. The flowers reſemble in general thoſe of the crowfoots, but differ ſomewhat from them in having the cup divided only into three parts, the petals being about eight in number, and narrower. This low plant runs very much at the root, and choaks all plants which are near it.

Bugle, middle conſound, ſicklewort, or herb carpenter. It riſes about half a foot high, with a ſquare ſtalk. The leaves come out by pairs, of a purpliſh colour, and indented about the edges. The flowers grow in a ſpike, are blue, and have a very ſmall upper lip.

Self-heal, hook-heal, ſicklewort, carpenter's herb, or prunell. This differs from bugle, in the leaves being longer and narrower: and in the flowers growing in a thicker ſpike; their upper lip being larger, and their filaments being forked.

Common yellow toad-flax, or flax-weed. It creeps very much with its hard woody roots; which ſend up ſeveral ſmooth ſtalks, a foot, or a foot and a half high, covered with long, narrow leaves, placed without order. The flowers grow in cloſe ſpikes, on ſhort foot-ſtalks, at the top of the ſtalks. They are of a light yellow, ſhaped like a calf's mouth; and end in a ſpur behind.

Ladies ſmock, cuckow-flower; in Norfolk, Canterbury-bells. The ſtalk is upright, round, and ſmooth. The leaves are winged, with the lobes of the lower ones roundiſh; and of thoſe upon the ſtalk oblong. The flowers are large, handſome, and white, or purpliſh; conſiſting of four obtuſe veined petals. The ſeeds are contained in erect, compreſſed pods, an inch, or an inch and a half long; divided into two cells: which, when ripe, burſt with a touch, and throw out their ſeeds to a conſiderable diſtance.

Crow foot crane's-bill, or blue crane's-bill. The leaves are divided, almoſt to the middle, uſually into ſeven parts. The ſtalk commonly divides into two branches, and each of theſe into two more. From the corner of each diviſion, comes a flower ſtalk; ſupporting two large blue flowers; conſiſting of five roundiſh, intire petals, ſucceeded by a long ſeed-veſſel, reſembling a crane's bill. This bill like ſeed veſſel is thick and rough; but not ſo long, as in ſome of the other ſorts.

Reſt harrow, or cammock, of the paſtures, differs very little from the corn reſt-harrow deſcribed before. The branches of this are armed with long ſtiff prickles. The flowers are of a higher purple, and come out ſingle: whereas, in the other, they come out two together.

Dandelion, or piſs a-bed, is well known in all paſtures, by its milkineſs, and its naked hollow ſtalks, ſupporting one large, yellow, compound flower; which is ſucceeded by a round ball of downy ſeeds.

Rough dandelion, or dandelion hawkweed. The whole plant is rough, with forked hairs. The flower-cup does not bend back, as in the common dandelion: and this is a taller plant.

Yellow devil's-bit, ſo called, becauſe the end of the root ſeems as if it were bit off, is alſo known by the name of ſmall hare's hawkweed. The leaves are ſmooth, long, narrow, and cut into long, ſharp-pointed ſegments. The ſtalks are a foot and a half, or two feet high, and branching. On the tops of theſe, grow many flowers, ſmaller and paler than in the dandelion; ſupported on ſcaly flower-ſtalks.

Long-rooted hawkweed. This has a very long tap root. The ſtalks are a foot and a half high, or more; cornered, naked, and divided. The bottom leaves ſpread in a circle on the ground, and are jagged and rough. The flower-ſtalks are ſcaly. The flowers, and down of the ſeed, reſemble thoſe of the dandelion.

Dwarf, or ſmall purple carline thiſtle. This lowly plant ſpreads its prickly leaves a foot round, and ſuffers nothing to grow beneath them. Its purple flower comes out in the midſt of theſe, without any ſtalk, cloſe to the ground.

Colt's-foot, fole-foot, horſe-hoof, or bull-foot. In February, the ſcaly ſtalks ariſe, bearing one yellow compound flower; which is ſucceeded by a hairy white down. The leaves come out later. They are ſhaped ſomewhat like a horſe's hoof; and are downy underneath.

Butter-bur, or peſtilent-wart, reſembles colts-foot in many reſpects; but the flowers are purple, and grow in a thyrſe. The leaves come out after the flowers decay; and are like thoſe of the colt's foot in ſhape; but are three or four times as big.

Ragwort, ragweed, ſtaggerwort, ſtanerwort, St. James's wort, ſeggrum, or ſeagrim. The ſtalk is uſually ſingle, round, ſtreaked, ſolid, and of a purpliſh colour, in ſome parts. The leaves are very much jagged, ſmooth, and of a dark green. The flowers are yellow, radiated, and grow many together. When we affirmed, that this plant comes up eaſily by hand, when young, or the ground is moiſt; we ſpoke from experience. The fact, in few words, was this. Some cloſes were notoriouſly over-run with this weed. The owner, juſt before the time of flowering, and after ſome rain, turned in a man and woman upon them; ordering the woman to pull up all ſhe could by hand; and the man to root out the reſt, with his docking-iron. The rag-wort was not, indeed, left in a lane, for the downy ſeeds to ripen; and to be carried on again to the cloſes, by the wind: but the plant was thrown in heaps, and burnt, and the aſhes were ſpread upon the graſs. It was not, indeed, all deſtroyed at this firſt attempt; but the few plants, which came up, the following year, were ſoon pulled up by the woman; and ſcarce a plant has now appeared in theſe cloſes, for ſeveral years paſt.

Fleabane, middle fleabane, or fleawort. The ſtalk is round, bending, ſolid, and hoary. The leaves are oblong, ſharp-pointed, wrinkled, downy, and embrace the ſtalk, on which they grow, very thick, without regularity. The flowers are yellow, radiated, and incloſed in a flower-cup, made up of narrow ſcales like briſtles. Mr. Ray tells us, that, if the leaves or tops of fleabane be ſqueezed, they ſmell like ſoap. Gerard ſays, the herb-women call it herb Chriſtopher.

Greater daſie, ox-eye, or maudlin-wort. The ſtalk is five cornered, ſolid, and branching. The leaves are jagged; and embrace the ſtalk. The flowers are large, and radiated. The ray is white; and the diſk yellow: the ſeeds have no down.

Common yarrow, milfoil, or noſebleed. The ſtalks are ſlender, round, ſtreaked, ſtiff, and hairy. They are divided towards the top into ſeveral branches; and theſe again into flower-ſtalks; ſupporting ſmall white or purpliſh flowers; growing thick together in a kind of umbel. The leaves are cut very fine; and divide twice.

Common, or black knapweed, matfellon, black matfellon, or bulweed. The root is hard, thick and woody; and has a diſagreeable aſtringency. The ſtalks are round, rough, ſtreaked, ſtrong, and very tough. The leaves are irregularly placed, oblong, and of a dark green. From the wings of the leaves, ariſe ſtalks, ſupporting one, two, or three heads of flowers; which are purple, and incloſed in a ſcaly cup. The ſcales are black, and ſurrounded with fine hairs, like the eye-laſhes.

The orchiſes may be known by their roots; which are either a double bulb, reſembling a pair of teſticles; or a bunch of long fleſhy roots, like the fingers of the hand. The flowers, by growing in a ſpike, make a handſome appearance. The colour is red in moſt ſorts.

Adder's tongue is hid among the graſs in low meadows. From a very low ſtalk, ariſes a ſingle, thick, ſmooth, oblong leaf; from the boſom of which, iſſues a kind of tongue, ending in a point, and indented on each ſide like a file.

WEEVIL, an inſect of the beetle kind, reſembling a ſmall May bug, with a long ſharp pointed head, to the hinder part of which are fixed two antennæ. It is black, and

and therefore eaſily diſtinguiſhed in any corn: but its principal and favourite food is wheat, of which, either old or new, it devours great quantities; without, however, communicating any bad ſmell to it, as the moth does. Some call it the corn-louſe, becauſe it bites animals more ſtrongly than fleas do. This has made it to be looked upon as a carnivorous inſect; and many have pretended that it devours both the worm and the chryſalis of the falſe moth: an opinion which M. Duhamel does not think improbable, becauſe, in effect, very few of thoſe moths are ever found in corn where there are many weevils.

Upon thruſting one's hand into a heap of corn, one may eaſily perceive, by its heat, whether it contains many of theſe inſects, which generally lie pretty much collected; and the particular places where they are moſt numerous, feel much warmer than the reſt. This obſervation ſoon led M. Duhamel to think, that a conſiderable heat is probably neceſſary for the hatching of their eggs; and that, in this caſe, even if they ſhould live, they will not be able to breed, in his ventilating granaries.

To aſcertain this fact, he put ſome weevils into wheat (not ſtove-dried) in one of thoſe granaries, in May 1751. It was well ventilated from time to time, and opened in Auguſt 1752, when none of them were found. He did the ſame with wheat which had been ſtove-dried; and when the granary was emptied, a year and half or two years after, not a weevil could be ſeen.

He again put ſome weevils into a ventilating granary in which wheat of the year 1754 was laid up, without having been ſtove-dried. This corn was taken out in May 1756, and ſifted over a fine ſcreen; which gave him an opportunity to obſerve whether the weevils had increaſed. Their number ſeemed to him nearly the ſame as that he had put in: and a farther reaſon which induced him to think they had not multiplied, was, that this grain, inſtead of being heated, as corn is well known to be whenever weevils breed in it, was ſo cool, that a country fellow employed for this work could hardly remain bare-footed among it.

In 1755; Dom Edward Provenchere, procurator of the Carthuſians of Liget, near Loches, in the Province of Touraine, intending to make ſome experiments on the preſervation of corn, choſe for that purpoſe a large caſk, at one end of which a little above the common bottom, he put a floor of lattice work, and over that a canvas. This caſk was filled with wheat of the harveſt of 1754, of which it contained 1080 pounds. He then fixed to it a pair of middle ſized bellows, ſo ſituated that they might eaſily be worked; and nearly in the centre of this corn, he put as many weevils as weighed ſix drachms; which is pretty conſiderable for that quantity of grain.

The bellows were blown an hour every week. In the beginning of September 1756, when that operation had been neglected for ſome time, the corn began to heat: but it was ſoon cooled again by uſing the bellows. The 15th of October, on taking the corn out of this caſk, in which it had kept perfectly well, not above twenty weevils were found in it. Dom Edward ſays he ſaw that inſect come out of the vent-holes every time the bellows were blown. He perceived in many places ſeveral grains of corn linked together by threads, certainly formed by moths that were in his wheat (which had not been ſtove-dried), and, not dying immediately, had had time to ſpin their web.

Dom Edward filled another caſk with nine hundred pounds of barley, not ſtove-dried, and put into it ſix drachms of weevils. Though care was taken to ventilate this caſk as much as the former which was filled with wheat, that is to ſay, during an hour every week, yet this corn heated prodigiouſly: the bellows could not cool it, and the weevils multiplied in it exceedingly.

"This, ſays M. Duhamel, is the very thing that happened to me in my larger experiment on the ſame kind of grain. Barley probably contains a great deal of moiſture; and the queſtion is whether ſtove-drying can be able to preſerve it. The increaſe of the weevils here ſeems to prove that this inſect cannot multiply in corn which retains a proper degree of coolneſs."

Though the above experiments ſeem to prove pretty clearly, at leaſt that the weevil cannot breed in corn which is kept properly cool, and that if any ſure way to deſtroy this inſect be ever diſcovered, it will be moſt likely to ſucceed by means of the ventilating granary; yet M. Duhamel, with his conſtant candour and unvaried zeal for the welfare of mankind, exhorts the naturaliſt, the philoſopher, the lover of the public good, not to rely too much on any thing that he has ſaid in this reſpect; to look upon the trials which he has related, as ſteps only which may help to lead to that deſired end; and to continue their endeavours to render to the world the important ſervice of ſhewing how this creature may be effectually exterminated, by any ſafe and practicable method.

"I have tried, continues he, in his lateſt writings upon agriculture, many of the receipts moſt vaunted in books of huſbandry, as remedies againſt the weevil, and have not found the leaſt benefit from any one of them. All that they have taught me, is that this animal will endure a great deal before it can be killed. It will live a long time without eating: cold will benumb it ſo as to make it appear to be dead; but I have put ſome of them, in that ſtate, into a warm place, and after keeping them there for ſome time, have found that they were perfectly alive: the great coolneſs of my granaries has ſeemed to prevent their increaſe; but it has not killed them. They bear eaſily a heat of from forty-five to fifty degrees of Réaumur's thermometer (from one hundred and fifteen to one hundred and twenty-four of Farenheit's). I kept corn in which there were many weevils, during half an hour, in a place heated to upwards of eighty degrees of Réaumur's thermometer (two hundred and ten of Farenheit's): ſome of them periſhed; but others remained alive. They, therefore, who would deſtroy them by ſuch a degree of heat, muſt let their corn be expoſed to it during ſeven or eight hours at leaſt.

"I grant that the ſmoke of ſulphur will kill any inſect; but that method is not practicable in granaries: for this vapour, which is very light, aſcends to the top of the granary, and ſcarcely acts at all upon the corn on the floor. It is true, that the corn may be ſo diſpoſed as to let this ſmoke paſs through it, and all the inſects in it will then be deſtroyed. But, at the ſame time, this ſmoke will give the corn a very diſagreeable and laſting ſmell, which depreciates it entirely. Conſequently this method will not do.

"It is confidently ſaid, that the weevils may be driven away by turning the corn with ſhovels rubbed with eſſence of turpentine. To try whether this eſſence really diſpleaſes them, I ordered two large caſes to be made: the inſide of one of them was rubbed with eſſence of turpentine;

tine; both of them were filled with corn in which there were many weevils; and the inſects remained as quiet in the one as in the other. It is true, that when corn infeſted with weevils is turned with a ſhovel, ſeveral of thoſe inſects quit the heap, and haſten towards the walls of the granary. This may have been imputed to the rubbing of the ſhovel with oil of ſpikenard or eſſence of turpentine: but the ſame thing happens when the ſhovel has not been rubbed with any drug whatever; and the fugitive weevils ſoon return to the heap of corn.

"When corn is ſifted in a ſieve (and the ſame is applicable to a ſcreen) fine enough to retain the grain; the weevils, then agitated, ſhrink up their legs, and are, in that poſture, generally ſo much ſmaller than the good corn, that very many of them drop through the ſieve. The greateſt part of them may therefore be deſtroyed by this method, which is a very good one: but, unfortunately, there will ſtill remain enough of them among the corn, to do conſiderable damage. This ſieve or ſcreen ſhould be of wire; and under it ſhould be placed an earthen or copper veſſel, pretty deep, to receive the inſects, and ſmooth on its inſide, to prevent their getting out eaſily.

"Of all the methods I have tried, that which has ſeemed to me to be the beſt, is to dry the corn in a ſtove, or oven, heated to eighty or ninety degrees of M. de Réaumur's thermometer (from two hundred and ten to two hundred and thirty of Farenheit's) and to let it remain there twelve hours. I exhort all thoſe who wiſh the welfare of the public, to ſtudy the means of deſtroying the weevil, and, in conſequence thereof, to make particular experiments: but I beſeech them not to publiſh their diſcoveries till they have made repeated trials of them, and that in different granaries: for I have ſometimes ſeen theſe inſects forſake a granary, when no cauſe could poſſibly be aſſigned for their ſo doing."

WELD, *or* DYER'S WEED, the name of a plant much uſed by the dyers to give a yellow colour to woollens, ſilks, cotton, and thread.

Its root, which is compoſed of a few ligneous fibres, does not pierce deep; from this root it puts forth leaves about four inches long and half an inch broad, of a lively green, ſoft to the touch, and ſpread circularly near the ground, with ſome gentle wavings at their edges, but obtuſe at their points. Its ſtem, which riſes from amidſt theſe leaves to the height of three feet, or even more if the ſoil and culture be very good, often branches out, and is garniſhed with leaves like thoſe below, though ſmaller in proportion as they approach the flowers, which grow in long looſe ſpikes at the end of the branches or ſtem. Theſe flowers, which appear at the latter end of June, are each of them compoſed of three ſmall irregular petals of a greeniſh yellow, to which ſucceeds a globular berry of the ſame colour, terminated by three points, and in which are incloſed ſmall brown ſpherical ſeeds. Theſe ſeeds ripen in September. The plant becomes entirely yellow when it is dry, and the whole of it, but eſpecially the berry, is uſed in dying. The ſlendereſt weld, and particularly if it inclines to a ruſſet colour, is accounted the beſt: that which is larger, and of a dull green, is much leſs eſteemed.

This plant grows naturally along the ſides of high-ways, upon dry banks, and on old walls, in many parts of England, France, Spain, and other countries where the winters are not very ſevere: but the cultivated ſort is far preferable to the wild, both for the quantity and the goodneſs of the colour which it yields. It will thrive tolerably on almoſt any ſoil, provided it be dry and warm: but the richer the land is upon which it is ſown, the greater will be the produce; and in proportion to the care with which it is cultivated, the more vigorous and fit for dying will it be.

The ground for this, as for every other plant, ſhould be in fine tilth at the time of ſowing it; though here, unleſs it be very poor indeed, it will not require dung. The ſeed ſhould be that of the preceding year; for if it be older, great part of it will not grow. Both Mr. Worlidge and M. Du Hamel are of opinion that weld ſeed ſhould, on account of its ſmallneſs, for it is but little bigger than that of purſlane, be mixed with aſhes, buckwheat, oats, or ſome other ſimilar ingredient, in order the better to avoid ſowing it too thick; for the plants of weld thrive beſt when they are about ſix inches aſunder. For this reaſon, as was before obſerved in regard to all plants which require being hoed, it is beſt to ſow weld in rows. Some ſow it on barley, or oats after they have been ſown and harrowed, this requiring only a buſh to be drawn over it; for it ſhould not be covered deep. A gallon of weld-ſeed thus uſed in the broad-caſt way will be ſufficient to ſow an acre of land. It will not grow much during the firſt ſummer, when it is thus ſown; but it will thrive a pace after the corn is taken off.

The beginning or middle of Auguſt is a proper ſeaſon for ſowing weld in this country. The only care that it requires whilſt growing, is to keep it clear of weeds which might choak it, or at leaſt weaken its growth.

The French, in general, ſow their weld in March, and pull it up in July or Auguſt of the enſuing year, when part of its ſeeds are ripe, and the plant is ſtill of a greeniſh yellow: they then dry it and threſh it upon cloths, to get the ripeſt of the ſeed, and after this they tie the ſtalks up in bundles, and ſell them to the dyers. But Mr. Miller rightly judges, that the beſt time to pull the weld for uſe is when it begins to flower, that is to ſay, about the latter end of June, becauſe, like all other vegetables, it is then in its greateſt vigour, and conſequently beſt fitted to yield the greateſt quantity of dye. For a produce of new ſeeds, it is much better to ſow a ſmall piece of land on purpoſe, or to ſet apart for this end a ſuitale portion of the field of which the plants are intended for uſe, rather than let the whole ſtand too long, that is to ſay, till part of the ſeeds are ripe; becauſe, by letting the plants ſtand till then, their quality is injured far beyond the value of the ſeeds that are got from them (the berries being, as was obſerved before, the part which yields the fineſt dye); and beſides, the ſeeds thus obtained will of courſe be a mixture of ripe and half-ripe ones, on the growing of which there cannot be a due reliance. The common way of drying theſe plants is to ſet them upright in ſmall handfuls in the field, and when they are dry, to tie them up in bundles. They muſt alſo be houſed dry; and care muſt be taken to ſtack them ſo looſely that there may be room for the air to paſs between them, to prevent their fermenting.

The plants which are intended for ſeed ſhould be pulled as ſoon as their ſeeds are ripe, and then be dried and beaten out for uſe: for if this is deferred, or if they are let ſtand too long, the ſeeds will ſcatter.

The method of cultivating this plant at Oiſſel, in Normandy, where great quantities of it are raiſed for exportation

tation to Holland, independent of the conſumption in France, is thus related by M. Dambourney, in the Memoirs of the Royal Society of Agriculture at Rouen.

" In the month of July, juſt after the kidney beans then in bloom have been hoed for the ſecond time, and earthed up, eſpecially if there be an appearance of approaching rain, weld ſeed is ſown among them, very thin, as equally as poſſible. Careful huſbandmen bury this ſeed by dragging over it a ſmall buſh of thorns. Whilſt the weld riſes, the beans ripen and are gathered; after which the ground remains, of courſe, planted with weld only. This is hoed about Michaelmas, then left in that condition during the winter, and in the enſuing month of March, when the danger of froſts is judged to be over, it is hoed again, to extirpate ſuch weeds as may have come up in the mean time. Towards the end of June in this ſecond year, when the weld has done bloſſoming, when its berries form, and when the plant begins to turn yellow, advantage is taken of the firſt fair day after a rainy one, to pull it up. Two men will then pull up as much of it in one day, as four men can when the ground is dry and hard. It is carried off in large bundles: but theſe are untied before the weld is laid up for keeping, and the plants are ſpread out and ſet upright againſt walls or hedges well expoſed to the ſun, the heat of which completes their drying in two days. They are then laid upon a cloth, to prevent the loſs of the ſeed, which drops very eaſily out of the now open capſules; and finally, after being tied up again in bundles weighing about thirty pounds apiece, they are piled up looſely in a barn or other well covered place, where they complete their ripening, and generally ſhrink to leſs than half of their former weight.

" Weld raiſed on rich ground is apt to be greaſy and too full of ſtalks: that which grows in ſandy places is of a better quality, and has only one main ſtem: but, in return, the produce here is much leſs than in the former caſe.

" As ſoon as the weld has been pulled, ſheep are turned in upon the land, to eat up the graſs it may have produced: it is then plowed once; and after another plowing at the end of October, it is ſowed with wheat, or great rye, without uſing any other compoſt or dung. If the land is light and deſtined for ſpring-corn, turnips may be ſown upon the firſt plowing after the weld; for they will have time to grow big enough to be pulled before the plowing for oats or ſmall rye, which laſt crops it will be proper to help with a little ſhavings or raſpings of horn.

" If it be intended to raiſe weld after peas, the ground ſhould be plowed, and the ſeed ſown very thin: to do which the more effectually, this ſeed, like that of turnips, ſhould be taken up only in pinches between the middle finger and the thumb, and the fore-finger ſhould remain extended, the better to help its ſpreading when it is dropped. This ſeed ſhould be ſown in rows ſufficiently diſtant for the plants to have full room to grow; and the beſt way is to leave an alley after every third row. When ſown, it is harrowed in, and the only farther care that the weld requires is to keep the plants free from weeds, by hoeing the ground at Michaelmas and in March, as before directed.

" The weld which is ſown after peas does not injure the land it grows on; and therefore in this caſe, as after the kidney-beans before ſpoken of, wheat may be ſown in October, without any previous manure."

WHEAT, the name of a well known plant, greatly cultivated in many parts of the world, eſpecially in England.

As a crop of wheat, is, in general, the principal riches of farmers whoſe farms conſiſt of arable land, we ſhall be very full in deſcribing every method yet practiſed with ſucceſs, for cultivating this uſeful ſpecies of grain; and in order to this, ſhall begin with the method of preparing the ſoil by ploughing, harrowing, and rolling.

Ploughing increaſes the food of plants, by opening the ſoil to receive the vegetable food from the air; and by enlarging the ſurface, and thereby expoſing a greater quantity of the ſoil to its influence.

Ploughing enlarges the paſture of plants, by opening the ſoil, if too ſolid, and making it firm, if too light.

Ploughing prepares the vegetable food for entering the roots of plants, by reducing vegetables to a ſtate of corruption, and diſſolving oils.

Ploughing deſtroys weeds, by making their ſeed vegetate, and then tearing up the young plants; and by expoſing their roots to the drought.

Ploughing removes wetneſs, by laying up land in proper ridges.

It may be ſaid, therefore, that ploughing is one of the moſt important operations in agriculture; and that the greateſt care is to be taken in the performance of it.

Though ploughing in general ſerves all the purpoſes mentioned, yet commonly one of them only is chiefly in view; and according to the deſign in view the work is to be performed.

When the deſign of ploughing is to increaſe the food of plants, the ſurface cannot be made too uneven; for the more uneven that the ſurface is made, the greater quantity of the ſoil is expoſed to the influence of the air, and the greater quantity of food procured.

When the deſign of ploughing is to enlarge the paſture of plants, that kind is beſt that goes deepeſt, (provided the ſoil allows,) and moſt effectually breaks the mold; for the deeper that the plough goes, the greater quantity of ſoil is employed in vegetation; and the more effectually that the mold is broken, the larger is the paſture in the ſame quantity.

When the deſign of ploughing is to deſtroy root-weeds, the ſurface cannot be left too rough, nor the earth of the furrow raiſed in too large pieces; for the rougher that the ſurface is, and the larger the pieces of earth raiſed, the drought has the eaſier acceſs, and more effectually operates in the deſtruction of the roots.

When the deſign of ploughing is to deſtroy ſeed-weeds, the ſurface cannot be made too ſmooth, nor the mold too much broken: for the ſmoother that the ſurface is made, and more effectually that the mold is broken, the ſeeds are the more expoſed to the influence of the air, the ſap better preſerved, and their vegetation the more encouraged.

When the deſign of ploughing is to remove wetneſs, the land muſt be laid up in high and narrow ridges; for the greater number that there are of furrows, there are the greater number of drains; and the higher that the ridges are, the more eaſily the water finds its way to the furrows.

Thus we ſee how this operation of ploughing is to be performed, according to the chief deſign in view. It often happens, however, that land is in ſuch a condition as to require more than one of theſe advantages which ploughing is intended to promote. Theſe are ſometimes

conſiſtent

conſiſtent with each other, and the land may be ploughed in ſuch a manner as beſt to promote all of them. Thus land is ſometimes, at the ſame time, poor, and wet, and full of root-weeds: now, it may be ploughed in ſuch a manner as is moſt proper for increaſing its food, removing its wetneſs, and deſtroying its weeds: for, by one ploughing, its ſurface may be made uneven, which fits it for receiving an increaſe of food; it may be formed into narrow and ſteep ridges, which beſt removes its wetneſs; and the earth may be raiſed in large pieces, which beſt expoſes the roots of the weeds to be deſtroyed by the drought.

At other times the land is in ſuch a ſituation, that the advantage which it requires from ploughing are inconſiſtent with each other, and it cannot be ploughed in ſuch a manner as is moſt proper for promoting all of them. Thus land at the ſame time, may be full both of ſeed-weeds and of rootweeds: now, it cannot be ploughed in ſuch a manner as is moſt proper to deſtroy both; for by one ploughing it cannot be raiſed in pieces and left rough, which is neceſſary to deſtroy root-woods, and have the mold broke and be made ſmooth, which is neceſſary to deſtroy ſeed-weeds. This makes it neceſſary to have one of theſe things chiefly in view at firſt, and to conſider which of the two it is proper to begin with, and how the work may be performed in ſuch a manner, as the other may moſt eaſily ſucceed. Thus, in the preſent caſe, the land ſhould be ploughed, ſo as to be raiſed in pieces, and to be left rough; and in that condition it ſhould be allowed to lie, till the drought may be ſuppoſed to have deſtroyed the roots; and then it may be reduced, the pieces broke, and the ſurface made ſmooth, in order to deſtroy the ſeeds.

In ploughing there are ſome general rules to be obſerved, whatever is the deſign of it. Thus land is never to be ploughed when it is wet. When land is ploughed wet, the deſign of ploughing, whatever it may be, is fruſtrated; and this holds true in every kind of ſoil.

When ſtiff ſoil is ploughed wet, by drying too ſuddenly it becomes ſo hard, that it can receive no benefit from the air, and the paſture in it is entirely ſhut up: root-weeds ſtrike root again before the drought reaches them; and if there are any ſeed-weeds, the ſurface cruſts ſo ſoon, that they are prevented from vegetating.

When light ſoil is ploughed wet, though it may receive ſome benefit by expoſing a larger ſurface to the influence of the air, yet its pores, being full of water, will prevent its paſture from being enlarged; and the root-weeds that are in it, will not be deſtroyed; they will rather flouriſh, by being tranſplanted into a new paſture. In both kinds of ſoil the labour is very ſevere upon the cattle, and the land is greatly damaged by their going upon it, and treading it down with their feet.

Thus it is alſo to be obſerved, that whatever is the deſign of ploughing, the quantity of firm land taken off from the ſurface of the plough in going, ought not to exceed the wideneſs of the furrow which the plough makes below. If it does, the land is not clean ploughed; it is only ſcratched, and a quantity of the ſoil is left below untouched betwixt every furrow that the plough makes.

The quantity of firm land to be taken off by the plough, depends upon the deſign of ploughing, and the nature of the ſoil.

When the deſign of ploughing is to increaſe the food of plants, and deſtroy root-weeds, whether the ſoil is ſtiff or light, as great a quantity may be taken off as the plough can take conveniently; becauſe the greater that the quantity is which the plough takes off, the rougher and more uneven the ſurface is made, the more food is procured, and the root-weeds more effectually deſtroyed.

When the deſign of ploughing is to enlarge the paſture of plants, and deſtroy ſeed-weeds, though a large quantity may be taken off in a light ſoil, that naturally falls in pieces when turned over, yet a ſmall quantity ought to be taken off in ſtiff land that is not ſo eaſily reduced; becauſe the ſmaller that the quantity is which the plough takes off, the ſoil is the more effectually broken, and the ſurface made the ſmoother; and the more effectually that the mold is broken, and the ſmoother that the ſurface is made, the paſture is the more enlarged, and the weeds more effectually deſtroyed. This is agreeable to the ordinary practice, introduced no doubt from experience; for we find that a much leſs quantity is taken off when land gets the ſeed-furrow, the chief deſign of which is to enlarge the paſture, than at any other ploughing.

In the directions which we have given about ploughing, we have had chiefly in our view land employed in tillage; it is neceſſary to add ſomething with reſpect to the ploughing lea, or opening up graſs ground.

The Engliſh writers on agriculture, when giving directions about the opening of graſs ground, always ſuppoſe that the land is to be ſummer-fallowed; and they recommend to plough as deep at firſt as the nature of the ſoil will allow. They aſſign this reaſon, That it is not poſſible to plough deeper afterwards. They likewiſe direct to turn the earth upſide down, or on its back, as we have called it. The reaſon they aſſign for this, is, that the ſward or turf may be the ſooner rotten.

Some perſons tried this method of breaking up graſs-ground in Scotland, but they found great difficulty in reducing it: and we have reaſon to believe that many find it ſo likewiſe in England; for Mr. Tull, in his chapter upon ploughs, tells us, That if the turf lie long without being turned, the graſs from the edges will ſpread and form a new turf, and that the roots often ſet up new heads, and the former heads are converted to roots. As Mr. Tull's deſign is to ſhow the neceſſity of the four-coultered plough, we need not doubt but he has a little exaggerated the matter; for, upon a narrow inſpection, it will be found, that if turf is turned upon its back, the graſs will grow only from the ſides. However, we may conclude, from what he ſays, that the land in England is not ſo eaſily reduced in this manner, as ſome pretend.

On the rich lands in Scotland, they follow a method the very reverſe of this which has been mentioned. They commonly ſow after one ploughing of graſs-ground, and plough as ſhallow and narrow as poſſible; and alſo ſet the turf as exactly as poſſible upon its edge. It is not our buſineſs in this place to conſider the propriety of ſowing after one furrow. We may only obſerve, that if the land is good, a good crop may be expected; and if there is a good crop, the turf will be completely rotten before next ſeaſon. What we have to conſider, is, which is the moſt proper method to break and reduce the turf. It is certain, that the thinner and narrower the turf is taken off, the more eaſily it is torn aſunder, and the more that it ſtands on its edge, the harrows in going acroſs take the firmer hold, and make the greater impreſſion.

If this kind of graſs-ground is ploughed before winter in the manner mentioned, ſhallow and narrow, and the turf ſet upon its edge, it may be expected, if we are favoured with

with a little froſt, that in the ſpring the turf will be in ſuch condition, as to be eaſily torn aſunder by the harrows, and the land itſelf in a proper condition to be ſown with oats, or to be ſummer-fallowed, and ſown with wheat.

Their barren lands they break up in the ſame manner as in England. They plough deep, and turn the turf over on its back. It ſeems, that the plants which grow on theſe lands have tougher and ſtronger roots than thoſe that grow on rich lands. This makes it more difficult to break the turf. If the earths of the furrows are ſet on their edge, the harrows turn them back, inſtead of tearing them aſunder. This happens whether the land is ploughed deep or ſhallow. But when the earths are turned on their back, and the land ploughed deep, the harrows raiſe a kind of mold upon the back of the turf, by which the hollows betwixt the earths are filled up, and nouriſhment afforded for the ſeed, the greateſt part of which falls into theſe hollows.

There is another method propoſed for opening up graſs-ground, and that is by trench-ploughing. This manner of ploughing is performed by one plough following another in the ſame track. The plough that goes firſt, turns over the ſward or turf; and the one that follows, turns up ſome inches of ſoil upon it. By this method there is ſufficient nouriſhment provided for the crop, and the ſward is rotten before next ſeaſon.

This kind of ploughing needs not be confined to the opening up of graſs-ground; it may be uſed in any ſoil that is deep; for by it ſome new ſoil is turned up, and a greater quantity employed in vegetation.

It has already been obſerved, that ploughing in ridges is proper for removing wetneſs. Every furrow becomes a kind of drain: the rain that falls upon the ridge, makes its way to the furrows, and by means of them is conveyed away from the field.

Ploughing in ridges is alſo proper for enlarging the ſurface. It is certainly an advantage to have the ſurface enlarged. Thereby not only a greater quantity of ſoil is expoſed to the influence of the air, but alſo a great quantity of it actually employed in vegetation. There is no more ſoil added to the field by enlarging the ſurface; but ſome of the ſoil that lies buried, while a field is in its natural ſtate, is expoſed to the air, and brought within reach of the roots of plants, when it is laid up in ridges. Some of the plants which we cultivate in our fields, have what are called horizontal roots, that is, roots that creep along the ſurface, and go down but a ſhort way. Now, it is obviouſly an advantage to theſe plants, to have a quantity of the ſoil below, to which their roots cannot extend, brought within their reach, which is done by enlarging the ſurface.

The tap-rooted plants, that is, ſuch as puſh one principal root perpendicularly downwards, have alſo horizontal roots, by which they are nouriſhed; and therefore it muſt likewiſe be an advantage to them, to have the ſurface enlarged.

To illuſtrate this further, let us ſuppoſe, that the roots of plants upon a field extend themſelves through the whole ſoil within four inches of the ſurface. Now, it is obvious, that there is more ſoil within four inches of the ſurface, when the ſurface is enlarged by ridges, than when the land is lying quite flat.

From theſe things then it appears, that a field contains more food, and has a larger paſture when in ridges, than when laid down level.

It muſt be acknowledged, that ſome conſiderable perſons are of a different opinion; and as this is the caſe, it will not be improper to conſider what is advanced by them.

There are ſome who mention the perpendicular growth of plants, as an evidence, that a ſurface, however much extended, can ſupport no more plants than the horizontal baſe. Though the fact is allowed, that plants grow perpendicularly, and that it is impoſſible to place more of them upon the ſurface than upon the baſe; yet it does not follow, that a field, when its ſurface is enlarged, can nouriſh no more of them; and it is to be remembered it is not more room which we contend for, but more nouriſhment. We may further obſerve, with reſpect to the growing of vegetables, that the enlarging the ſurface has this other advantage; it gives the plants more air, and thereby prevents them from falling down and lodging.

Mr. Du Hamel, to ſhow that the enlarging the ſurface by ridges is a real diſadvantage, obſerves, that ſuppoſing the ſlope in ridges is one foot in ſix, yet the ſurface will be to the horizontal baſe only as ſeventy-ſix to ſeventy-five, which he ſays, is but a ſmall advantage, when compared to the loſs by the furrows.

In anſwer to this, it needs only be ſaid that there is no loſs by the furrows, unleſs when they are a real advantage to the reſt of the field. When land is dry, the corn is as good in the furrows as in any part of the ridge; and when the land is wet, the furrows ſerve for drains, and the loſs by them is more than made up by the advantage which the reſt of the field receives by being drained.

We may therefore conclude in the general, that the way of ploughing in ridges is preferable to the way of ploughing without ridges.

Having ſhown, that ridges are advantageous, as they remove wetneſs, and enlarge the ſurface, it is neceſſary now to conſider what kind of ridges are moſt proper for anſwering the ends propoſed.

As ridges remove wetneſs, when the ſoil is wet, the ridges ought to be narrow; for the greater number there are of ridges, there are the greater number of drains. When the ſoil is wet, the ridges ought alſo to be ſteep. For the ſteeper that the ridges are, the water more eaſily finds its way to the furrows.

When the ſoil is very dry, it is ſubmitted, if narrow ridges are not proper likewiſe. For by altering the ridges, and turning the furrows into the crowns, and the crowns into the furrows, a quantity of freſh ſoil is always employed in vegetation. When the crown of a ridge is turned into a furrow, it is obvious that ſome freſh ſoil is turned up, which was not employed in vegetation in its former ſituation; and the greater number there are of ridges, there is the greater quantity of freſh ſoil employed.

When the ſoil is juſt ſo wet as to occaſion loſs in the furrows, then the ridges ſhould be ſomewhat broader. For, in this caſe, the fewer there are of furrows, there is the leſs loſs.

It is proper to obſerve here, that a difference ſhould be made betwixt the ſituation of land in the winter, and its ſituation in the ſummer. It may be convenient ſometimes, when winter-grain is to be ſown, or when the land is to get winter-fallowing, to make the ridges very narrow; and, when ſummer-grain is to be ſown, to make them broader.

As it is an advantage to have the ſurface enlarged, the ridges ought to be made high in the middle, or crown.

For the higher that the ridge is made, the more is the ſurface enlarged.

When the ſoil is ſhallow, the ridges, if broad, cannot be raiſed, without depriving the furrows of ſoil: and therefore, to enlarge the ſurface on ſuch land, the ridges muſt be made narrow. For this both enlarges the ſurface, and prevents the furrows from going below the ſoil.

When the ſoil is deep, the ridges may be made broader: for though the ridges are raiſed in the crown, yet ſtill there is ſoil left in the furrows. But then the ridges muſt not be made too broad: for it is evident, that narrow ridges give more ſurface than broad ridges, of the ſame degree of ſteepneſs; and do not cover the lower parts of the ridges ſo much from the influence of the ſun and winds.

It is neceſſary to obſerve, that though, in the general, it is recommended to raiſe the ridges in the crown, to enlarge the ſurface, and to allow the water more eaſily to find its way to the furrows; yet, in ſome low flat-lying land, it is proper to make the ridges as flat as poſſible, in order to raiſe the furrows. For the higher that the furrows are raiſed, there is, in ſome caſes, the greater command of the water, and it is the more eaſy to find a fall for conveying it away.

It is neceſſary to obſerve likewiſe, that flat ridges have this advantage over ſteep ridges; they can be ſown with greater exactneſs. It is obvious from the method of ſowing, that, in ſowing ſteep ridges, it is not poſſible to prevent a great proportion of the ſeed from falling into the furrows. It is obvious likewiſe, that this proportion is increaſed by harrowing. Whereas, in ſowing flat ridges, the ſeed is equally ſcattered, and the harrows do not remove it from its place.

From theſe obſervations, it is obvious, that ſoils in different ſituations require to be laid out in different kinds of ridges. It is abſurd, therefore, to aſſert, that, in every caſe, one kind of ridges is preferable to another; that narrow ridges are better than broad ridges, and flat ridges better than ſteep ridges. In ſome ſituations, one kind of ridges is moſt proper; and, in other ſituations, another kind is moſt proper. Every perſon ought, therefore, to conſider the nature of the ſoil he has to deal with, conſider the advantages and diſadvantages of each kind of ridges, and then determine which are moſt proper.

When there is nothing in the nature of the ſoil to determine what kind of ridges are moſt proper, then narrow ridges are to be preferred; for this reaſon, that a quantity of land in narrow ridges is ſooner ploughed than when in broad. It is obvious, that the two firſt furrows which the plough takes off from the ridge, are wider than any taken off afterwards, eſpecially if the plough begins in the furrow, as is frequently the caſe; ſo that the greater number there are of ridges, the field is the ſooner ploughed. Beſides, when ridges are broad, it is obvious, that the plough has more work, and muſt take longer time in turning, than when they are narrow. But then it is ſuppoſed that the ridges are ſtraight and equal. If they are not, the greater number there are of them, the greater is the trouble, and the more time is ſpent in ploughing. This, however, it muſt be owned, is of no great importance; becauſe it ſeldom happens, that the kind of ſoil does not determine what kind of ridges are moſt proper.

Having conſidered the kinds of ridges proper for land, according to its different ſituations; it is proper to inquire, whether there are any qualities which ridges ought to have, whatever is the ſituation of the land.

It will eaſily appear, that all ridges ought to be made ſtraight. Crooked ridges, it is obvious, are attended with ſeveral inconveniencies. In plowing them, the cattle are not always going exactly in the ſame direction with the plough; ſhort turnings are often neceſſary, as fields are generally bounded by ſtraight lines, or lines not crooked in the ſame manner with the ridges; and, when there is a ſmall deſcent, the water, as it runs in the furrows, meets with reſiſtance.

It is obvious, that when the plough goes in a curve, as it does in ploughing crooked ridges, the draught is not in the ſame direction with the beam, but is either to the right or left of it; and this gives the plough either too much or too little land.

It is obvious likewiſe, that, when ridges are crooked in a manner different from the lines by which a field is bounded, in ploughing the ridges upon the ſides, one part of them muſt be finiſhed before ſome other parts are near done; and thus ſhort turnings are neceſſary, which hurt the land much by the treading of the horſes.

It is obvious likewiſe, that, as a crooked furrow is continually altering the direction of the water, and has a leſs deſcent than a ſtraight furrow, the water, as it runs along it, muſt meet with greater reſiſtance, and thus penetrates the ſoil, and makes it more difficult to convey it away.

Theſe inconveniencies are removed by making the ridges ſtraight. For, in plowing ſtraight ridges, the cattle are always going in the ſame direction with the plough; no ſhort turnings are neceſſary, as fields can be made of an equal breadth in all places; and the furrows having a greater deſcent, the water meets with leſs reſiſtance, and is more eaſily conveyed away.

Straight ridges not only remove the inconveniencies with which crooked ridges are attended, but it is found that they are to be attended with no inconveniences themſelves: they require indeed a little attention in the ploughman, which is itſelf an advantage; and therefore, upon all occaſions, are to be preferred.

As, in all kinds of ſoil, ridges ought to be ſtraight, ſo likewiſe they ought to be equal, equal one to another, and the ſame ridge equally broad in all places. Unequal ridges are attended with inconveniencies, as well as crooked ridges. It is difficult to ſow them with exactneſs; it is difficult to alter them, when neceſſary; and the plough muſt often turn in the middle of the ridge, which does great harm, by the treading of the horſes, or it muſt be driven empty to the end.

Theſe inconveniencies may be removed by making the ridges equal. Equal ridges may be ſown with greater exactneſs, and conſequently with leſs ſeed; it is eaſy to change them, one into two, or two into three, as occaſion requires; and the ſame furrow that finiſhes the ploughing of the ridge in one place, finiſhes it in all places; ſo that there is no neceſſity to turn the plough in the middle of the ridge, or to drive it forward the ſhorteſt ſpace, without turning up a furrow.

In many places of England and Scotland the ridges are ſtill crooked and unequal; and, in many places, they are much broader, and much higher raiſed in the crown, than the nature of the ſoil allows. Were the ridges altered, and the fields laid down in a proper manner, as the ſoil requires, it would be a great advantage. At the ſame time, it may be obſerved, that much harm is done, by proceeding in this matter with too much precipitancy. It is neceſſary,

ceſſary, therefore, that we conſider it as an affair of ſome importance.

It is neceſſary to obſerve, in the firſt place, that ridges muſt not be raſhly altered: on the contrary, great caution is to be uſed.

If the ſoil is very dry, ridges may be altered without great danger, though high; and they may be made ſtraight without being levelled. For, though the old furrows are ſtill lower than the reſt of the field, yet this is attended with no bad conſequences in dry land; and by degrees, they are filled up in ploughing. But then, it is to be obſerved, that there is not much land in Scotland, on which the ridges, at preſent, are high raiſed, in its nature ſo dry, as to allow this to be done.

If the ſoil is wet, the ridges cannot be made ſtraight till the ground is level, without great danger. For the water will lodge in the hollows of the old furrows, from whence it will not be poſſible to force it. Some perſons that make their ridge ſtraight before they are ſufficiently levelled, draw water-furrows along the hollows of the old furrows, to carry off the water that is apt to lodge there. This is of ſome uſe, but does not fully anſwer the purpoſe. A quantity of looſe earth, in ploughing, is thrown into the old furrows. The water, as it falls, penetrates this looſe earth, and is retained by it, notwithſtanding the water-furrows. Beſides, theſe water-furrows muſt be nearly cleaned out with a ſpade, and made deeper in the places where they are intercepted by the crowns of the new ridges, otherwiſe they are of very little uſe.

Before ridges can properly be made ſtraight, it is neceſſary therefore that the land be made as level as poſſible.

But it muſt be obſerved, that it is as dangerous to level ridges raſhly as to alter them before they are levelled: for if ridges are levelled too faſt, and thereby a great depth of looſe earth thrown ſuddenly into the furrows, it will not be poſſible to convey away the water that falls upon them. The water as it falls will ſink to the bottom, and there will lodge and chill the ſoil; and the earth thrown into the furrows being looſe, the cattle in ploughing muſt ſink to the bottom likewiſe, by which the land is very much poached.

It is recommended therefore to every perſon, ſeriouſly, to conſider the nature of the ſoil he has to deal with, before he proceeds to the altering old ridges; and if the ſoil is wet, to level the ridges very gradually. When the ſoil is deep, and inclining to be wet, and a ſufficient ſlope for carrying off the water, it is probable, that the loſs ariſing from the levelling ſteep and broad ridges ſuddenly, may exceed the profit of many years ariſing from the ridges being properly laid down; and therefore, if a view to incloſing makes it neceſſary to ſtraight the ridges, the levelling them ſhould be the work of ſeveral years. Even ſuppoſing that the ſoil is ſhallow, and the ridges raiſed ſo high, that there is nothing but graſs left in the furrows, yet ſtill it is improper to level the ridges too faſt, though levelling in this caſe is neceſſary.

In levelling ridges a great hollow is made in the crowns. This is occaſioned by frequent ſucceſſive cleavings, which is the method commonly uſed for levelling ridges. It is obvious, that by the firſt cleaving a hollow is made in the crown of the ridge equal to the depth and breadth of the furrow which the plough makes; whereas the parts on each ſide of the ridge are but little levelled, and at each ſucceſſive cleaving this hollow is made greater. Such a quantity of new earth immediately turned up, is not fit for vegetation. Beſides, this hollow becomes ſo great, and the parts of the ridge on each ſide of it becomes ſo ſteep, that it is impoſſible to plough them in a proper manner.

In this caſe, when levelling is ſtill thought proper, ſome furrows from each ſide muſt be thrown back by the plough into this hollow, by which a new ſmall ridge is formed upon the crown of the old one, and then the remaining parts of the ridge may be levelled as before. Some perſons, inſtead of this, plough acroſs the ridges. This method ſerves the ſame purpoſes; it both throws ſome earth into the hollows, and levels the ridges; for the plough in going carries off ſome earth from every height, and leaves ſome in every hollow. But then land muſt not be left in this ſituation during the wet ſeaſon, unleſs water-furrows are drawn along the furrows, and alſo in ſome-caſes along the crowns; for unleſs this is done, the water that falls upon the field cannot be conveyed away. At the next ploughing, the whole old ridges may be levelled in the ſame manner as at the firſt ploughing; or, if thought more proper, may be divided into two equal ridges, ploughed in ſuch a manner that the furrow betwixt them may be exactly in the crown of the old ridge, and the other furrows exactly in the furrows of the old ridge. By this operation the old ridge is raiſed from the furrows, and levelled from the crown.

When a perſon is upon a ſcheme of levelling, this method of dividing the ridges into two will be found very proper, either when winter-grain is to be ſown, or when the barley-land gets the winter-ploughing.

Though land may be in ſuch a ſituation as to allow the ridges to be levelled with ſafety, yet unleſs it is remarkably dry, and in no caſe in danger of being damaged by too much water, the ridges ſhould not be altered, excepting when the land is ſummer-fallowed; and in that caſe, beſides the ploughing that alters the ridges, there ought to be another before the wet ſeaſon comes on, that ſo the bottom may be ſufficiently firm to reſiſt the water.

We have obſerved, that ridges ſerve to remove wetneſs, and to expoſe the ſoil to the influence of the air, and we have ſhown what kind is moſt proper for theſe purpoſes. But this is not enough; it is neceſſary likewiſe to conſider in what manner ridges ought to be placed. This is a matter of ſome conſequence: for, according to the poſition of ridges, water may be either conveyed away or retained; and ſome aſſert likewiſe, that by this the ſoil may be better expoſed to the influence of the ſun and wind. Theſe things therefore muſt be kept in view in the placing of ridges.

When the land is wet, as is often the caſe, it is certain that ridges ought to be placed with a view to the conveying away the water: but when land is dry, as is ſometimes the caſe, then ridges ſhould be placed with a view to the retaining the water.

The moſt common way of placing ridges where there is a ſlope, is along the declivity in a ſtraight line from the top to the bottom; and land is commonly laid out with a view to this. Where the declivity is gentle, this is, no doubt, a very proper way of placing the ridges; but if the declivity is great, this way of placing the ridges allows the ſoil to be waſhed away by the rain. It is obvious, that water, in running off of land, carries a part of the ſoil along with it, and the quantity is great, in proportion to the violence with which it runs. In climates where there are heavy

ſhowers of rain, the damage done by this is not inconſiderable. Therefore, in this caſe, placing ridges acroſs the declivity is the moſt proper way; for when ridges are placed acroſs, the water meets with many interruptions in its courſe, and does not run off with ſuch violence as when placed along from top to bottom, and therefore does not carry off ſuch a quantity of the ſoil along with it.

Inſtead of this ſome perſons make the ridges very narrow. This ſerves the ſame purpoſe; for in proportion to the number of furrows, there is the leſs water in each furrow, and conſequently it runs with leſs violence. However, placing the ridges in this manner is not ſo proper for this purpoſe as placing them acroſs the declivity, and, beſides, is not ſo proper for retaining the water in a dry ſeaſon.

When land is very dry, and in no danger of being damaged by the ſtagnation of water, the ridges ought to be placed acroſs the declivity, as near the level as poſſible; for this retains both the water and the ſoil. It is obvious, that when ridges are placed in this manner, the water cannot get off by running along the ſurface, by which the ſoil is in the greateſt danger of being carried away. As the furrows ſtop it in its courſe down the hill, it can get off in no other way than by penetrating the ſoil. By this a part of it is retained; what of it gets off is clear, and carries no ſoil along with it.

When land is dry at the head of the ridges, and wet at the foot, and no proper fall for carrying off the water, as is frequently the caſe, the ridges ſhould be placed in the ſame manner, directly acroſs the declivity. For, in this caſe, every furrow in ſome meaſure retains the water that falls upon the ridge above, and thereby prevents it from ſinking towards the bottom of the field, and lodging there. By this way of placing the ridges, the dry part of the field is rendered wetter, and the wet part of the field is rendered drier than otherwiſe they would be.

This is likewiſe a very proper way of placing the ridges, even when the declivity is but ſmall, if the land is in the ſituation mentioned, dry at the head, and wet at the foot. It muſt be owned, however, that this will not entirely anſwer the end propoſed: for the water will penetrate the ſoil; and when it is reſiſted by till or clay, will find its way along theſe to the bottom of the field. But this will not be ſo ſudden, as in the other way of placing the ridges: and the ſoil at the head, which is naturally dry, will receive more benefit from the rain as it falls.

When land is wet, and the water may be conveyed away from the bottom of the field, the ridges ſhould be placed acroſs likewiſe; not directly, but with a ſmall ſlope to a drain or furrow on the ſide of the field from top to bottom, by which the whole water is conveyed away. In this caſe every furrow becomes a drain to the ridge below, and prevents the water from running over it.

When land is wet from the breaking out of ſmall ſprings, this way of placing the ridges is alſo very proper. The furrows convey away the water as it riſes, and prevent it from doing any damage.

It is neceſſary to obſerve, that ridges placed in this manner, to ſerve theſe purpoſes, ſhould not be altered; for when the furrow is kept in one place, it is a more proper drain than when altered. When the furrows are kept in one place, the bottom is always firm, and the water runs eaſily along it; whereas, if changed, it may fall upon places of the field, where the ſurface, being raiſed by former ploughings, will prevent them from reaching the firm bottom. Beſides, if the ſprings break out in the furrows, by changing their place, they may break out in other parts of the ridge.

It is neceſſary to obſerve likewiſe, that ridges placed in this manner ſhould not be raiſed in the crown, but kept quite flat; that ſo, by the natural deſcent of the ground, the whole water that falls upon the ridge may be conveyed into the furrow below.

It was before obſerved, that ſome perſons aſſert, that, by a proper poſition of ridges, the ſoil is better expoſed to the influence of the ſun and air. Theſe perſons recommend the paying a regard to this. But it cannot be done excepting when the land is quite flat, and when the placing of the ridges makes no difference as to its wetneſs. However, as this is repreſented by thoſe perſons as important, ſome attention ſhall be given to what they ſay.

Some adviſe the placing the ridges ſouth and north; and the reaſon which they aſſign for this, is, that thereby the ſun may have an equal influence upon all parts of the ridge.

Others, again, adviſe the placing the ridges eaſt and weſt; and the reaſon which they aſſign, is, that they may ſhelter each other from the cold north wind.

Which of theſe advantages is the greateſt, is uncertain. It is even uncertain whether they can be called advantages at all.

It may be diſputed, whether, in the winter-ſeaſon, cold or heat is moſt beneficial to land. That heat is beneficial and cold deſtructive to plants, is certain. But cold poſſibly may be as proper as heat for preparing land for the nouriſhment of plants. It is allowed, that the coldneſs of the north wind is, in ſome meaſure, owing to the quantity of ſalts that it carries along with it. Theſe ſalts are beneficial to land; and therefore an expoſure to the north ſeems to be rather a benefit than a diſadvantage. This is confirmed from obſervation. The lands on the north ſide of riſing grounds are, generally ſpeaking, more fertile than thoſe on the ſouth-ſide. It is certain, that the richeſt lands in Scotland have this ſituation, and are expoſed to the north.

It may be diſputed likewiſe, whether the north or the ſouth-ſide of an eaſt and weſt ridge has moſt benefit from the ſun in ſummer. It is not to be denied, that the rays of the ſun fall more directly on the ſouth ſide of the ridge; but then let it be obſerved, that the north ſide has the benefit of the ſun's rays in the mornings and evenings, when the ſun is ſo low, that the ſouth ſide is under the ſhade; which may poſſibly balance the loſs ſuſtained by the greater obliquity of the ſun's rays about mid-day.

Theſe things have been mentioned, to ſhow, that it is uncertain, which way of placing ridges expoſes the land beſt to the influence of the ſun and air; and therefore, that, in placing them, it is needleſs to have any view in this. When the placing of ridges makes no difference as to the wetneſs of land, then we are chiefly to have in view the conveniency of ploughing and laying out the land in proper breaks.

There are three different ways of ploughing ridges: gathering, caſting, and cleaving.

Gathering keeps the crown and furrows of the ridge in the ſame place in which they were before. The plough begins in the crown, and ploughs out the ridge, turning the earth towards the crown, where it entered. Every ridge is ploughed by itſelf; or, inſtead of this, the halves of two contiguous ridges may be ploughed together. By this method of ploughing, the ridge is higher raiſed than before.

before. It is obvious, that, as the earth on each ſide is turned upon the crown, and thrown up out of the furrows, the ridge is raiſed, both by making the crown higher, and the furrows lower.

Caſting keeps the crowns and furrows likewiſe in the ſame place, in which they were before. The ridges are ploughed in pairs. The plough may enter in the furrow betwixt the ridges, and plough out the ridges, turning the earth towards the furrow, where it entered. Or the plough may enter in the furrow on the right ſide of the two ridges, then turn to the one on the left, and plough out the ridges, turning the earth to theſe furrows, and from the furrow that is betwixt them. By this method of ploughing, the ridges are kept of the ſame height in the crown, and one of the furrows made a little higher, and the other a little lower than before. The earth is taken from one furrow, and thrown into the other, and this is done alternately through the field. If this is reverſed at next ploughing, that is, the earth turned into the furrows from which it was taken at the former ploughing, thereby the ridges are preſerved in the ſame ſituation.

Cleaving is the reverſe of gathering. The plough enters in the furrow on the right ſide of the ridge, turns to the furrow on the left ſide, and ploughs out the ridge, turning the earth from the crown towards the furrows. Every ridge is ploughed by itſelf; or, inſtead of this, the halves of two contiguous ridges may be ploughed together. If the ridge is raiſed in the crown, by this method of ploughing it is made flatter. It is obvious, that, by this method of ploughing, earth is thrown into the furrows, by which they are made higher; and that earth is taken from the crowns, by which they are made lower. If the ridge is already flat, by this method it is changed, and the crown turned into the furrow.

When a field is laid out in the manner judged moſt proper, with reſpect to the breadth and height of the ridges, it ſhould be ploughed in one or other of theſe ways mentioned, according to its ſituation. If the ridges are broad and high, caſting will be found to be the moſt proper method of ploughing. For this is the only way by which they can be ploughed, and yet kept in the ſame ſituation: cleaving will make them flatter; and gathering will raiſe them higher. If they are flat and narrow, cleaving will be found to be the beſt method. Cleaving flat ridges, and thereby turning the crowns into furrows, and the furrows into crowns, has theſe peculiar advantages: a field is much ſooner ploughed in this way, than in any other; and a quantity of freſh earth, at every ploughing, is expoſed to the air, and employed in vegetation: and the ridges being kept level, are ſown with exactneſs. In no caſe gathering is proper, unleſs when the proper ſituation of the ridge renders it rather too wet for winter grain.

It may not be improper, in this place, to conſider a method of ploughing, uſed in ſome places, called ribbing. This method of ploughing is performed by making furrows about two feet diſtant from each other: one half of the ſurface is untouched by the plough, and the other half, which the plough turns up in making the furrows, is thrown on the top of what remains faſt. The land may be ploughed in this manner, either without regard to ridges; or the plough may be made to enter and turn, as it does in gathering, caſting, or cleaving; that is, a ridge may be ribbed in the way of gathering or cleaving; and two ridges may be ribbed in the way of caſting. This kind of ploughing is ſeldom practiſed, but in the beginning of winter, and upon land to be ſown with barley, after two more clean ploughings. It does not prevail ſo much as formerly, and is very much condemned by our modern improvers. But, however much it may be condemned, it certainly has its uſes. It keeps the land dry; the rain that falls is confined to the furrows, from whence the looſe earth is taken, and eaſily finds its way off. It facilitates the rotting of the ſtubble, by covering it and keeping it dry; it makes the froſt penetrate a greater quantity of the ſoil; and it alſo expoſes a larger ſurface to the influence of the air. Theſe things make this kind of ploughing, in ſome caſes, preferable to a clean ploughing.

There is alſo another method of ploughing called bouting. It is performed by throwing the earths of two furrows towards each other upon ſome faſt land. This is certainly an improvement upon ribbing, and better anſwers all the purpoſes of it.

By this method ribs are placed where furrows were before, and furrows where ribs were before; and the ſurface is entirely changed, what was above turned down, and what was below turned up. Theſe two ploughings may be performed with the ſame ſtrength, and in the ſame time with one clean ploughing; and, it is probable, that, upon trial, in ſome caſes, will be found more beneficial.

As a further improvement of this method of ploughing, it is propoſed to rib the land, and, at the ſame time, to plough it clean. This is done by throwing the earths of three or four furrows together in ſuch a manner, as to leave no faſt land below; and is the ſame thing with ploughing the land in ridges about three feet broad, from the middle of one furrow to the middle of the other. This ſerves all the purpoſes of the other kinds of ribbing, and, beſides, has theſe further advantages; the land being clean ploughed, weeds are more effectually deſtroyed, and the ſoil is better opened for receiving benefit from the froſt and air. This method may likewiſe be reverſed by another ploughing. The ſurface may be entirely changed, and the ribs turned into furrows, and the furrows into ribs.

Theſe different methods of ploughing, the laſt two excepted, are known to every common ploughman, and they ſhould be attended to by every improver, as of importance; without a proper knowledge of them he cannot give directions to his ſervants, nor prevent them from falling into blunders in the execution, which they are but too apt to do. The ignorance of a maſter in things which his ſervants are acquainted with, is attended with bad conſequences; it gives them an indifferent opinion of his knowledge of farming, and makes them deſpiſe every new thing which he propoſes, as abſurd and whimſical.

It was obſerved, that ploughmen are apt to commit blunders in ploughing. Thus in gathering ridges, if care is not taken in beginning the ploughing of the ridge, ſome firm land will be left in the crown, and the crown itſelf ſo much raiſed above the reſt of the ridge, that no ſeed will lie upon it. It is ſometimes obſerved, that juſt on the crown of a ridge, where the ſoil is deepeſt, there is leſs corn, and more root weeds, than in any other part of the ridge. This is certainly occaſioned by allowing firm land to remain there in ploughing, and by raiſing the crown like a peak above the reſt of the ridge. The ploughman, inſtead of turning back the earth of the firſt furrow, and the firm land below it, keeps at ſuch a diſtance, as to lay the earth of the ſecond furrow up to it, or on the top of it. This leaves firm land betwixt the furrows, and raiſes the

crown

crown of the ridge to a peak. But if he is directed to draw the furrows ſo near, as to turn back the earth of the firſt in making the ſecond, no firm land will be left, and the earth, that by the other method is thrown upon the crown, will be ſcattered.

This blunder is oftener committed when flat ridges are cleaved. In cleaving, if the ridges are ploughed out turning the plough always to the left, it is impoſſible to prevent the two furrows, laid together in the crown of the new ridge, from being at too great a diſtance, and raiſed higher than the reſt of the ridge. When ridges are cleaved in this manner, the earth of the firſt furrow that the plough makes, is turned over upon firm land, and backed by the earths of the other furrows in their courſe. This makes it impoſſible to get at this firm land in ploughing the next ridge, without turning up the firm land itſelf, and the earth of the furrow laid over it, upon the top of the earth of the ſecond furrow, by which the crown of the ridge would be raiſed to a high ſharp peak. Now, to prevent this, the ploughman, in ploughing the next ridge, keeps at a proper diſtance, and does not touch the firm land, over which the earth of the firſt furrow is laid. But it may be obſerved, that he muſt either keep at ſuch a diſtance as to leave firm land in the crown of the new ridge equal to the breadth of two furrows, or he muſt turn the earth of his furrow upon the top of the earth of that firſt furrow. By this the crown of the ridge is ſtill high raiſed, and ſome firm land ſtill left.

But ridges of this kind may be cleaved without leaving any unploughed land, or without raiſing the crown much above the reſt of the ridge. The method of doing it is this: after the plough has made the firſt furrow, inſtead of turning to the left, and making a furrow on the other ſide of the ridge, it turns to the right, and throws back the earth of its firſt furrow along with the firm land below it, and after going round again in the ſame courſe, turns to the other ſide of the ridge, and goes twice round in the ſame manner, after which the ridge betwixt the two fierings, as they are called, is ploughed out, as at firſt propoſed. When the ploughing of the ridge is finiſhed, a new fiering is made in the next furrow, by the plough going twice round, as before directed, and then the ridge betwixt the laſt-made fiering and the ploughed land is ploughed out in the ſame manner as before; and in the ſame way the fierings are made till the whole field is ploughed. By this method there is no firm land left below the earth of the furrow; and the earth that is turned towards the crown being ſcattered, and not laid all in one place, the crown itſelf is not much raiſed above the reſt of the ridge.

It may be obſerved likewiſe, that in caſting ridges, if care is not taken, the furrow towards which the earth is thrown will be ſo filled up as to be improper for a drain. The plough enters the ridge near the furrow, and throws the earth towards it, turns to the right, and throws the earth from the oppoſite ſide towards it likewiſe; and then goes in the tract of the old furrow, betwixt the earths of the furrows made on each ſide. This furrow, towards which the earth is thrown, is ſometimes ſo filled up as to render it improper for a drain. We have ſhown how the earth around it is ploughed. The furrow which the plough makes going in the track of the old furrow, betwixt the earths of the furrows on each ſide, is called a gore-furrow. On the left ſide, the plough having no mold-board, the looſe earth falls back into the furrow behind the plough, and fills it up, or at leaſt makes it unfit for a drain, which in wet land is a great diſadvantage.

But this may be prevented by proper care; the furrow may be made clean, and fit for a drain. The method of doing it is this: the plough enters about two feet from the furrow, and inſtead of turning to the other ſide, returns on the ſame ſide, turning back the earth, and then goes round again in the ſame courſe; after this turns to the other ſide of the furrow, and does the ſame, going twice round. By this the gore-furrow is made quite clean, and, like the crowns of ridges, formed at about two feet diſtance on each ſide.

Some other things of a like nature might be mentioned. Theſe have been inſiſted upon, to ſhow, that it is neceſſary to attend to every circumſtance of ploughing, that ſo this important work may be performed in the moſt proper manner.

The chief deſign of harrowing land is, to ſmooth the ſurface. By this weeds are deſtroyed, and ſeed, if ſown, is covered.

Root-weeds, that are looſed by the plough, are ſometimes torn up by the harrow, and thus are deſtroyed. When this is the deſign of harrowing, the harrows ſhould go acroſs the ridges, or rather acroſs the way that the plough has gone. Becauſe, by going acroſs the earths of the furrows, the teeth of the harrow are apter to catch hold of the roots, than if it ſhould go in the ſame way with the plough.

Though the harrow may bring ſome part of the roots above ground, yet commonly ſome other parts continue below, which will grow if undiſturbed. This makes it neceſſary for perſons to follow the harrows, and gather all the roots which they obſerve brought up, and carry them off the field, or burn them.

If harrowing does not actually tear up the roots, it encourages their vegetation, by filling up the hollows, and thereby defending them againſt their greateſt enemy, the drought. On this account harrowing is improper for deſtroying root-weeds, excepting after a ſpring-ploughing, when the land is ſoon to be ploughed again for ſeed. For at this ſeaſon the drought is ſeldom violent, and it has not time to operate in the deſtruction of the roots; and therefore whatever the harrows bring out is ſo much deſtroyed.

The ſame things that make harrowing improper for deſtroying root-weeds, make it very proper for deſtroying ſeed-weeds. The ſmoother that the ſurface is made, and the more effectually that the mold is broke, the ſeeds near the ſurface are the more expoſed to the air, and the ſap, which is in the land, the more effectually retained. Both theſe are neceſſary to promote the vegetation of the ſeeds; and they muſt vegetate before they can be deſtroyed. But harrowing not only promotes the vegetation of the ſeeds of weeds, but alſo deſtroys the young plants when ſprung up; ſo that one ploughing, if the ſeaſon is favourable, and ſoil allows, may be attended with ſeveral harrowings, and thereby ſeveral crops of weeds deſtroyed.

If land riſes in hard clods, the harrow makes but little impreſſion; at leaſt before the clods are broken, the land is made ſo firm by the treading of the horſes, and the weight of the harrows, as to render the work uſeleſs, and ſometimes deſtructive. Great care ſhould therefore be taken to prevent land from being brought to this ſituation. If land once riſe in hard clods, it is vain to expect to break them with the harrow, ſo as to cover the ſeed. Unleſs the

ſeaſon

ſeaſon is very wet, it will remain in this ſituation throug n the ſummer, and afford but little nouriſhment for the crop. Sometimes it will remain in this ſituation after men have attempted to break the clods with malls.

If the ſoil is light and ſpungy, it can ſcarcely get too much harrowing; for the more that it is harrowed, it becomes the firmer. But if the ſoil is ſtiff, the leſs harrowing it gets the better, if the purpoſes propoſed are anſwered. The effects of harrowing are in this caſe contrary to thoſe of ploughing. Ploughing renders ſtiff ſoil more free and open, but harrowing renders it ſtill more firm and ſolid.

The ordinary way of harrowing after ſeed is ſown, is firſt along the ridges, then acroſs, and then along again. If ridges are flat, they may be harrowed either along or acroſs; and the work may be begun or ended either way. But if the ridges are ſteep, it is improper to begin by harrowing acroſs, becauſe thereby too much of the ſeed will be drawn into the furrows. If the ridges are very ſteep, for the ſame reaſon, it is improper to harrow acroſs at all. For another reaſon it is thought improper to harrow acroſs ridges when the land has been ploughed immediately out of lea or graſs. In ploughing this kind of land, the ſward is for the moſt part turned over whole; ſo that when the harrow goes acroſs, inſtead of tearing the ſward, it is apt to turn it back into the furrow from whence it was taken. When ridges are gathered or caſt, this will probably happen. In caſting, the earths of the furrows on one ſide of the ridge are turned towards the crown; and, in gathering, the earths of the furrows on both ſides are turned the ſame way; and therefore the harrows, when drawn from the crown to the furrow, are apt to take hold of the unbroken ſward, and turn it back. But this does not ſo readily happen when the ridge is cloven. Becauſe in cleaving, the earths of the furrows on both ſides of the ridge being turned from the crown, the harrows, in going up from the furrow, are not in ſuch danger of turning them back. In ploughing lea, the earths of the furrows are ſometimes placed as exactly as poſſible upon their edge, that ſo they may be the more eaſily torn by the harrows. When theſe are turned to the crown, they do not ſupport each other; and are therefore eaſily turned back by the harrow, in going from the crowns to the furrows: but when the earths are turned to the furrows, ſo they ſupport each other by their weight; and therefore are not ſo eaſily turned back by the harrows in going up from the furrows to the crowns.

Rolling of land is practiſed with ſucceſs, both on land lying in graſs and on land in tillage. It is of advantage to land in graſs, by preſſing down mole-hills and mole-runs. Some ſay, that it alſo deſtroys fog.

When land is laid down in graſs for hay, rolling is of uſe in ſmoothing the ſurface; and, when laid down in graſs for paſture, it makes the graſs ſtool, or tiller, and grow thicker.

There is a kind of land, which, when clover is ſown upon it, throws out the young plants after froſt. Rolling, in the beginning of winter, and immediately after the froſt is gone, it is ſaid, will, in ſome meaſure, prevent this. The firſt rolling prevents the froſt from penetrating ſo deep, as otherwiſe it would do; and the ſecond makes the land firm, after having been looſed by the change from froſt to open weather.

Rolling may alſo be uſed with advantage upon land in tillage. When the land is naturally ſtiff, and may be reduced by the harrow, rolling is very improper: for it makes this kind of land ſtill firmer than the harrow does. But if the land riſes in clods, which the harrow does not reduce, rolling is very proper; for it ſmooths the ſurface, and breaks the clods, more effectually than harrowing.

When the land is light and ſpungy, the roller ſhould always be applied after ſeed is ſown; for it is ſcarcely poſſible to make this land too firm.

It was obſerved, that, to deſtroy root-weeds, land ſhould be made rough, and raiſed in as large pieces as poſſible; and that it ſhould be allowed to lie for ſome time in that ſituation. Rolling, after this, is of great uſe; for, without it, if the weather continues dry, it will not be poſſible to make the land fit for receiving another ploughing.

If the land is ſoft below, and ſome hard clods upon the ſurface, which the harrow does not break, rolling may be uſed with ſome advantage: for, beſides ſmoothing the ſurface, it will break ſome of the clods; and ſuch of them as are preſſed down, will be diſſolved by the natural fermentation of the ſoil, if in good heart.

Sometimes in ſtiff land, ploughed, dry, after a former wet ploughing, or when, by any accident, it has been much trod upon, the whole riſes in hard clods, which the harrows cannot break, ſo as to cover the ſeed. In this caſe rolling is of great uſe. It bruiſes ſome of the clods; and, when followed by the break-harrow, theſe clods are raiſed up and broken. Though rolling ſhould do no ſervice but ſmooth the ſurface, yet, on that account, it ſhould be practiſed. For when the ſurface is ſmooth, the corn may be cut down more expeditiouſly than when it is rough and uneven. When graſs-ſeeds are ſown for hay, it is abſolutely neceſſary to ſmooth the ſurface: the roller is moſt proper for this. Some uſe it before, and ſome after ſowing. When it is uſed before ſowing, the ſeed is more equally ſcattered.

Graſs-ſeeds muſt be ſown in ſuch a manner as to lie near the ſurface; otherwiſe they will not vegetate. The making the land firm by rolling is therefore an advantage, as, by it, the ſap is better preſerved; and this does not ſo much damage to graſs as to corn, for the ſeveral kinds of it are commonly better foragers.

But however all the operations of ploughing, harrowing, and rolling are performed, ſomething will be ſtill wanting to promote vegetation, and this want is effectually ſupplied by certain ſubſtances called manures. To apply theſe ſubſtances in ſuch a manner, as moſt effectually to promote vegetation, it is of importance to know their natures, and the ways in which they operate. This is the more neceſſary, as, without it, we cannot know how to apply them in the moſt proper manner to the different ſoils.

Manures operate, by communicating to the ſoil with which they are mixed, the vegetable food which they contain; by communicating to it a power of attracting this food in greater plenty from the air; by enlarging the vegetable paſture which it contains; and by diſſolving the vegetable food which it is already poſſeſſed of, and fitting it for entering the roots of plants.

Manures are very different in their natures. Some of them operate in all the ways mentioned; and there are none of them that do not operate in more ways than one.

Great miſtakes have ariſen from ſuppoſing that manures operate only in one way. None have been attended with greater loſs, than ſuppoſing that they ſerve only to divide the ſoil, and that tillage may be ſubſtituted in their place.

This

This is Mr. Tull's opinion, and is, indeed, the fundamental principle of his horſe-hoeing huſbandry.

Before one changes the ordinary practice of agriculture, in ſo important a point as baniſhing manures from his fields, the good effects of which are ſo obvious; he muſt be certain, that the principle which determines him to ſo important a change, is itſelf well-founded.

Mr. Tull has endeavoured to prove, that earth is the food of plants; and hence infers, that to divide the earth into minute particles, by which it is fitted for entering their roots, is all that is neceſſary in agriculture: and this, he aſſerts, may be done by tillage, without manures.

When treating of the food of plants, we have attempted to ſhow, that other principles, beſides earth, are in the compoſition of this food: and, if this is true, the want of manures, which provide theſe other principles, cannot be ſupplied by tillage.

But ſuppoſing we allow, with Mr. Tull, that earth is the food of plants, yet ſtill it does not follow, that tillage may ſupply the place of manures. It is certain, that every particle of earth which we obſerve, is not of the kind that is the food of plants. Every ſoil is a compoſition of different earths; ſeveral of which, it is obvious, are not of this kind.

The great difference in ſoils equally pulveriſed, is a plain and convincing evidence of this. Now, let it be obſerved, that the earth contained in dung is of this kind; it has already been food to plants, and therefore though all that is contained in the greateſt quantity of dung laid on at one time, is but ſmall in proportion to the quantity of ſoil employed in vegetation, as Mr. Tull juſtly obſerves; yet it may be conſiderable in proportion to the quantity that is really the food or pabulum of plants. If the quantity of earth contained in the quantity of dung commonly laid on at one time, is compared with the quantity of earth contained in the richeſt crop, it will be found ſeveral times larger; and therefore, by the laying on of this dung, food is provided for ſeveral good crops.

Beſides, let it be obſerved, that the mechanical action of the plough cannot increaſe the number of the particles by which plants are nouriſhed; they are ſo ſmall as not to be obſerved in water. Mr. Tull ſuppoſes, that they are as ſmall as thoſe upon which the colour of bodies depends. Now, though pounding earth in a mortar may perhaps do ſomething to increaſe them, yet the action of the plough can never be ſuppoſed to do it. The plough can do no more than open the ſoil, or enlarge the paſture of plants, and allow them to extend their roots in ſearch of their food, but does not increaſe the quantity of it; and therefore tillage cannot ſupply the place of dung, which not only opens the ſoil by its fermentation, but alſo increaſes the vegetable food by the earth which it contains.

It may further be obſerved, that the fermentation raiſed by dung continues for a conſiderable time; ſo that though, by ploughing, the ſoil may be as completely divided as by the fermentation of dung, yet it will not continue ſo: for after ſeed is ſown, the artificial paſture raiſed by ploughing is continually decreaſing while the crop is growing; whereas the artificial paſture, raiſed by the fermentation of dung, is continued by the continuance of this fermentation; and therefore, though in the horſe-hoeing huſbandry the want of dung may be ſupplied by hoeing, yet, as Mr. Tull indeed obſerves, dung is ſtill neceſſary in the old huſbandry.

If perſons attentively conſider the effects of manures, it will appear that they operate in all the ways mentioned.

Manures are found to enrich the beſt pulveriſed ſoil, and to do this again and again, after it is exhauſted by crops. It is almoſt an univerſal practice in Scotland, to lay dung upon land that is kept conſtantly in tillage once in three, four, or five years. It is obſerved, that after the dung is laid on, the land becomes rich, and that the crops turn gradually worſe and worſe, till the whole virtues of the dung are exhauſted; and it is alſo obſerved, that immediately upon the dung being again applied, the land becomes rich as before. It is natural to conclude from this, that dung promotes vegetation by increaſing the quantity of the vegetable food.

It is found, that ſome manures loſe part of their virtues by being long expoſed to the air. After dung is ſufficiently rotten, the longer that it lies it becomes of leſs value, and does not enrich ſo large a quantity of land as when uſed in proper time. The dung of cows dried upon their paſture, gathered, and laid upon other land, is ſcarcely to be diſcerned in its effects on the crops produced: the ſame quantity applied, whether carried from the byre, or by folding the cattle, enriches the land. From this it is obvious, that this kind of manure contains the vegetable food in itſelf, and does not receive it from the air.

It is found, that ſome manures operate the ſooner, and with the greater violence, the longer that they are expoſed to the air before they are uſed. Lime and marles are of this kind; the longer they lie expoſed, they operate the ſooner; and it is obſerved, that they have a ſtrong power of attracting the virtues of the atmoſphere. From theſe things it is reaſonable to infer, that theſe manures operate, by communicating to the ſoil with which they are mixed, a power of attracting the vegetable food from the air.

It is obſerved, that ſome manures exhauſt land of its vegetable food, and do not reſtore it again when immediately applied. This is found to be the caſe with lime. Land thoroughly limed has been found to carry many very good crops: by degrees however the virtues of it have been exhauſted, and the land reduced to a worſe ſituation than before the lime was laid on. In this ſituation lime has been applied a ſecond time, but its effects found to be far inferior to what they were when firſt applied. This is ſufficient to convince us, that this manure operates by diſſolving the vegetable food which it meets with in the ſoil, and fitting it for entering the roots of plants.

It is certain, that all kinds of manures open the ſoil. Any perſon will be convinced of the truth of this, who will take the trouble to compare a piece of land, on which dung, or any other manure has been laid, with a piece contiguous that has not been manured; he will find the one much ſofter, much more free and open than the other. It muſt be allowed, therefore, that all manures operate by enlarging the vegetable paſture.

Manures are commonly divided into claſſes. Some divide them into natural and artificial; others divide them into the foſſil, the vegetable, and the animal; and treat of them in order, as belonging to each of theſe claſſes.

The manures belonging to ſome of theſe claſſes, differ both in their nature and operation from thoſe in the other claſſes. Some of them likewiſe differ from others in the ſame claſs. The dividing them into claſſes, therefore, ſerves no purpoſe. All that is neceſſary is, to treat of the different particulars which the farmer can command, without conſidering to what claſs they belong.

The

The manures generally procured are dung, marles, aſhes, ſoot, ſea weed, ſhells, ſown vegetables, and water.

There are ſeveral other things that are very rich manures, ſuch as rags, leather, &c. But as theſe are to be procured only in ſmall quantities, it is needleſs to treat of them ſeparately.

Dung is commonly uſed to ſignify not only the excrement of animals, but alſo all rotten vegetables, when uſed as manures.

Dung is the food by which animals are nouriſhed, reduced to a corrupted ſtate. The ſtomach diſſolves the food of the animal, and reduces it to a ſtate of putrefaction much ſooner than is done by the air. It is by being in this ſtate of putrefaction that the juices fit for the nouriſhment of the body are conveyed by the guts into the blood. While bodies are in a ſound ſtate, their parts adhere firmly together, and they are incapable of being turned into the parts of other bodies. To render them capable of this, they muſt be reduced to their firſt principles. This is done by corruption. It is obſerved, that by corruption all the parts of bodies are relaxed, and the ſalts, oils, and other juices which they contain, from being fixed, are made volatile. It is by being reduced to this ſtate in the ſtomach, that the things which the animal feeds upon become nouriſhment to it, and are turned into parts of its body.

All the juices contained by the things which animals feed upon, are not exhauſted by the guts; many of them, along with the earthy part of the food, are thrown out. There is no doubt that ſome of the earthy part of the food goes alſo to the nouriſhment of the animal; but as the earth is rendered volatile by the ſalts and oils, there muſt be but a ſmall quantity of it in proportion to the quantity of theſe exhauſted by the animal; and therefore in the dung there muſt be a great quantity of earth in proportion to the other principles. However, as the dung contains all the principles of the food, we may conſider the dung of thoſe animals that feed on vegetables as vegetables in a putrefied ſtate.

Of the ſame nature is the dung of animals that feed upon other animals. Vegetables are the original food. All animals either feed on pure vegetables, or on other animals that feed on vegetables. Animals that feed on vegetables are made up of the ſame things with vegetables, only under a differennt form; and therefore the dung of animals that feed upon theſe, is ſtill to be conſidered as vegetables in a putrefied ſtate.

Chemiſts inform us, that dung is compounded of the ſame principles of which vegetables are compounded, of water, air, oils, ſalts, and earth. The earth which it contains is of the abſorbent kind, and attracts the other principles. They alſo inform us, that dung attracts and ferments with acids, and by this fermentation produces ſalts. A quality of ſalt, as was before obſerved, is to attract and diſſolve oils, and make them capable of being mixed with water.

If theſe qualities of dung are conſidered, it will appear that it promotes vegetation in all the different methods before-mentioned.

It promotes vegetation by increaſing the vegetable food. It is compounded of the ſame principles of which the vegetable food itſelf is compounded, as we endeavoured to ſhew, when treating of the food of plants. This is alſo confirmed by the experience of all places and of all ages; and it is what no perſon will doubt of, who conſiders that it has the ſame effects upon land of all kinds, and in all ſituations.

It promotes vegetation by enlarging the paſture of plants, it attracts acids from the air and ſoil; and by raiſing a fermentation with them, thereby ſeparates the particles of the ſoil with which it is mixed. Every farmer knows the truth of this from experience. The land upon which dung is laid, though naturally ſtiff, becomes ſoft and mellow, and is more eaſily ploughed than before.

Dung, we have ſaid, enlarges the paſture of plants, by attracting acids, and fermenting with them. Theſe acids are in the ſoil and air. They are in the ſoil; for the ſoil produces acid plants. Chemiſts tell us, that the neutral ſalt found in ſoil is compounded of an alkaline ſalt, ſuch as is found in vegetables, and an acid ſpirit. All alkalis are ſtrong attractors of acids, ſo that, in the proceſs of an experiment upon ſoil, perhaps it may be difficult to keep them ſeparate, though they may exiſt ſeparate in it. The acid plants prevent theſe from mixing; or, perhaps, have a ſtronger power in their veſſels to ſeparate them, than other plants have.

But though there may be no acids in ſoil, excepting in the compound of neutral ſalts; yet there is no doubt, but they are in the air. Chemiſts find this by innumerable experiments. Aſhes, when expoſed to the air, produce neutral ſalts; the application of acids has the ſame effects. Any perſon may obſerve a ſalt adhering to the lime of old walls; this ſalt is not in the lime, it is produced by the air. The ſame ſalt is produced by acids. Other experiments might be mentioned, but theſe are ſufficient.

Dung promotes vegetation, by communicating to the ſoil a power of attracting the vegetable food from the air. The earth which it contains, is of the abſorbent kind, and attracts all the other principles of the vegetable food; and the ſalts which it contains and produces, attract oils.

It likewiſe promotes vegetation, by preparing the vegetable food for the nouriſhment of plants. By the ſalts which it contains and produces, it not only attracts oils, but alſo diſſolves them, and makes them capable of being mixed with water. It is probable, that oil is a principal part of the food of every plant which we cultivate in our fields, at leaſt is the ingredient of which it is eaſieſt to exhauſt the ſoil, and which it is moſt difficult to reſtore to it again. In proportion to the quantity of oil contained in any plant, in proportion it robs the ſoil by which it is nouriſhed of its vegetable food. But the nature of oil muſt be changed before it can enter the roots of plants. This change is made by ſalts; they diſſolve it, and make it to mix with water.

Though dung promotes vegetation in all theſe ways mentioned; yet, as there are other bodies, that are much ſtronger attractors of acids, by which many of its effects are produced; it is probable, that it principally operates by increaſing the food of plants. Its effects in diſſolving the vegetable food in the ſoil, muſt be very trifling. The ſalts which it contains and produces, having its own oils to work upon, and being along with them conveyed into the roots of plants, cannot operate with any violence upon the oils which the ſoil contains. This is confirmed by experience. When the virtues of dung are exhauſted, the ſoil is no poorer than before it was laid on.

Some new improvers are pleaſed to ridicule the old farmers, bacauſe they are ſo fond of dung; but none will do this who attentively conſider the virtues of it. Such other manures as can be obtained, are to be uſed; and tillage is careſully to be attended to: but none of theſe are

to ſuperſede the uſe of dung, which can be employed to ſo great advantage.

Though dung in general has all the qualities mentioned, yet there are ſome kinds of it poſſeſſed of ſome of theſe qualities in a higher degree than others. There are as many kinds of dung as there are of animals, and in ſome reſpects they all differ one from another.

The difference betwixt one kind of dung and another, is commonly ſuppoſed to ariſe from the different food of the animals. Green herbage, ſtraw, or hay, do not contain ſo much vegetable food in the ſame quantity as grain does. Hence it is ſuppoſed, that the dung of cows is not ſo rich as that of horſes, nor the dung of horſes ſo rich as that of fowls.

But this difference muſt partly ariſe likewiſe from the nature of the animals, if it is true, that the dung of horſes, cows, ſheep, hogs, and geeſe, all differ one from another, though fed upon the ſame paſture. Some animals digeſt their food more quickly than others. This makes a difference in the dung produced by the ſame food. Some things are digeſted, and turned into a ſtate of corruption by ſome animals, that paſs through others found and undiſſolved. The matter then in the ſtomach that digeſts the food, muſt be different in the different animals. The dung muſt partake ſomething of the nature of this, which makes another difference in the dung produced by the ſame food.

Some writers in agriculture treat of the dung of the different animals ſeparately. But it is needleſs to do this; for it requires more pains and expence to keep them ſeparate, and uſe each of them by itſelf, than all the advantages ariſing from this way, above the ordinary way, can poſſibly amount to.

The dung of fowls, particularly of pigeons, is an exception to this. It is commonly uſed without any mixture, and it can be kept ſeparate from other dung without any trouble or expence. It is obſerved, with reſpect to it, that the effects of it are more violent, and ſooner over, than the effects of common dung. The effects of ſome other kinds of dung would perhaps be the ſame, if they were uſed without any mixture. The pigeons dung, being thoroughly corrupted ſoon diſſolves, and becomes vegetable food. But the ſtraw, with which the other kinds of dung are commonly mixed, not being ſo thoroughly corrupted, prevents the effects of them from being ſo violent, and ſo ſoon over.

The way in which pigeons dung operates, points out the manner in which it ſhould be applied. As it is very rich, and its qualities ſoon exhauſted, a very ſmall quantity ſhould be applied, in proportion to the quantity of other dung. If care is not taken of this, the crop will be deſtroyed by being too luxuriant. Perhaps, mixing it with ſome other things may have good effects. The ſtrewing ſmall chaff of any kind, from time to time, on the bottom of the pigeon-houſe, is very proper. The chaff ſucks up the moiſture, and makes it eaſy to reduce the dung to powder, which is an advantage: for thereby the dung is ſcattered more equally, and manures a greater quantity of land.

It is a cuſtom in ſome places, to fold ſheep and cattle, for the ſake of their dung; which, in this way, is uſed without any mixture. Some writers on huſbandry give particular directions how to do this in the moſt advantageous manner. But it is needleſs to conſider theſe. The farmer muſt conſult the advantage of his ſheep and cattle, and not the advantage of the land by the dung; and, therefore, muſt fold them in the moſt convenient manner. A ſcore of ſheep, with the beſt management in folding, will not produce much more than ten ſhillings worth of dung, in the ſeaſon, above the expence of folding; a ſum ſoon loſt by an injudicious management of them.

Dung is commonly mixed with vegetables, and allowed to lie for ſome time before it is uſed.

Straw is thrown below the cattle, and this is carried out along with the dung, and thrown upon the dunghill. On the dunghill is alſo thrown all the ſtraw that is left after ſerving other purpoſes, and all the refuſe of vegetables and animals, uſed in the farmer's family.

In the management of dunghills, two things are always to be kept in view: the promoting putrefaction; and the preventing the vegetable food from flying off into the air, or being conveyed away by water. The ſtraw and other parts of uncorrupted vegetables, of which the dunghill is compounded, make it neceſſary to keep the firſt in view; and the ſalts and oils, which by corruption are rendered volatile, and the water, which extracts the virtues of dung, make it neceſſary to keep the laſt in view.

To promote putrefaction, the ſituation of the dunghill ſhould be dry, and the dung laid together as thick as is convenient. Putrefaction, indeed, cannot be promoted without water: but the quantity that falls in rain, with the natural ſap of the dung, is ſufficient for this purpoſe. Too much water prevents that fermentation, which carries on the proceſs of putrefaction moſt quickly. This is confirmed by experience. If there is any part of a dunghill ſoaked with water, it is obſerved that the ſtraw is quite ſound, while, in other parts that are dry, it is completely rotten.

To promote putrefaction, the dung ſhould be laid thick together; thereby the heat is the ſooner generated, that produces the putrefaction; and thereby the natural ſap is the better preſerved, which prevents the dung from being burned.

When the natural ſap of the dung is exhaled, and the dung afterwards covered, the heat is in danger of riſing to ſuch a height, as to burn the dung. This muſt be carefully guarded againſt: for, when the dung is burned, its ſtrength is exhauſted, and it is rendered almoſt uſeleſs. Dung, in this ſituation, is dry and white; the ploughmen call it fire-fanged. When thus burnt, it is found, from experience, that it has loſt almoſt all its virtues. To prevent the dung from being reduced to this ſituation, when it is carried out of the ſtable or byre, particularly if there is much ſtraw in it, it muſt not be laid in heaps, which makes it dry too faſt, but carefully ſpread thick upon the top of the dunghill. This prevents the ſap from being carried off by the wind, and thereby prevents the heat from being raiſed to ſuch a height as to burn the dung.

It may be obſerved, that, when graſs is cut green, and immediately thrown into a heap, it heats, and this heat ſoon reduces the graſs to a ſtate of putrefaction. But, if the graſs is for ſome time expoſed to the air, and then put together without being ſufficiently dry, it heats alſo; but, inſtead of being reduced to a ſtate of putrefaction, is burned. So it is with dung: if, when carried out, it is laid in ſmall heaps, being thereby too much expoſed to the air, it loſes its ſap; and, being afterwards covered, the heat is raiſed to ſuch a height, as to burn it: but, if it is ſpread thick upon the top of the dunghill, it retains the ſap, and putrefies.

A diſ-

A diſtinction is here made betwixt dung putrefied and burned; and this diſtinction is repreſented as important. We know not if the chemiſts make any ſuch diſtinction. A late author ſays, that the greater part of what remains of dung, after the putrefaction is completed, ſeems to be earth, and a fixed alkali. Theſe things, we apprehend, make up the greater part of what remains, when dung is what we have called burned; but when it is only putrefied, it contains alſo ſalts and oils. But though chemiſts ſhould make no ſuch diſtinction, it is abſolutely neceſſary that the farmer do it: for, when the dunghill is allowed to heat to ſuch a degree, as to burn the dung, the value of it is thereby greatly leſſened.

To prevent the vegetable food from being conveyed away, no foreign water, excepting what falls in rain, muſt be allowed to run into the dunghill; and the ſituation of the dunghill, if poſſible, ſhould be high at the ſides, and hollow in the middle. When foreign water is allowed to run into the dunghill, the fermentation is not only ſtopped, but, as it is often neceſſary to allow the water a paſſage from it, thereby much of the vegetable food is conveyed away. When the bottom of the dunghill is quite level, the rain, which ſometimes falls in heavy ſhowers, eaſily finds its way off; but this is prevented by making it high at the ſides, and hollow in the middle.

The only way to prevent the vegetable food from being exhaled by the ſun, or carried off by the wind, is to cover the dunghill. The covering the dung would certainly be an advantage, if it could be eaſily executed. If it was not for the additions that are daily made to it, earth would be very proper for this purpoſe. Some perſons aſſert, that, by covering the dunghill, it would loſe the influence of the air; and it is the air alone, they ſay, that makes it fit nouriſhment for vegetables; and, therefore, recommend the expoſing it, particularly to the north and north-eaſt; becauſe the wind from theſe points brings along with it more aëreal nouriſhment than from the others. If the dunghill contained no vegetable food, but what it received from the air, this direction would be very proper; but, as the dunghill contains in itſelf all the ingredients of the vegetable food, and as its juices, the more it is putrefied, become the more volatile, the vegetable food in it by being expoſed to the air, inſtead of being increaſed, would be diminiſhed. The covering the dunghill, therefore, would be an advantage. But the difficulty lies in executing this.

Some propoſe to dig a large pit, lay the bottom with flags, build up the ſides with ſtones, and cover it with a roof. This, it muſt be owned, will retain the juices, and promote corruption, as well as prevent the vegetable food from being exhaled. But then it muſt be ſo expenſive, that few will be engaged to make trial, unleſs the benefits are more obvious than the aſſertions of the contrivers make them: and, beſides the expence, it muſt likewiſe be attended with inconveniencies. In ſome ſituations, it will be very difficult to prevent too much water from getting into it; and as difficult to get the dung itſelf carried out.

The method which we propoſed for preventing the dung from over-heating, will alſo, in a great meaſure, ſerve this purpoſe. The dung, when it comes from the ſtable or byre, is mixed with ſtraw, which abſorbs the juices, and prevents them from flying off, till the ſtraw itſelf begins to putrefy. When, in this ſituation, it is laid thick upon the top of the dunghill, a ſmall ſurface only being expoſed to the air, and being covered before the ſtraw begins to putrefy, the juices, in a great meaſure, are preſerved. A perſon, by the ſmell, is ſenſible that the juices of the dung are not ſo volatile, when firſt laid upon the dunghill, as after they have been covered for ſome time, and then expoſed to the air.

Dung, expoſed to the ſun and wind, or waſhed by rain, loſes its vegetable food; it ought, therefore, to be ploughed in as ſoon as is poſſible, after it is laid upon land. Some perſons aſſert, that they have found from experience, that dung is nothing worſe, though it lie a conſiderable time ſpread upon land, in dry weather, before it is ploughed in. This, if true, is contrary to what has been ſuppoſed, that the vegetable food is exhaled by the ſun, and carried off by the wind. It is probable, that, after dung is ſpread upon land, its fermentation ceaſes, and the ſalts and oils remaining in it may become fixed, and may continue ſo till a new fermentation is raiſed by mixing the dung with the ſoil; and that, by attracting acids from the air, more ſalts may be formed. By this its effects will be more ſudden and violent, but ſooner over.

It may be proper alſo to obſerve, that as the juices contained in the dung are waſhed downwards by the rain, it ſhould be ploughed in with a very ſhallow furrow; excepting when the dung is not ſufficiently rotten. In this caſe it requires a deep furrow to cover it.

The better that dung is mixed with ſoil, the purpoſes of vegetation are the better anſwered; all parts of the ſoil receives equal benefit, the vegetable food is equally diſtributed, and in all parts the fermentation equally promoted. When dung then is laid on land, it ought to be ſpread as equally as poſſible. This likewiſe prevents the breeding of vermin, which happens in ſome ſoils, when the dung is left in too large pieces.

Some are of opinion that lime is only a ſtimulus, that is, that it promotes vegetation, only by making the ſoil with which it is mixed, exert itſelf. Others, that it promotes vegetation by enriching the land, and adding to the quantity of vegetable food.

They firſt ſupport their opinion by obſerving, that the crops which lime enables land to produce, exhauſt it in a remarkable manner. It is a certain fact, that land thoroughly limed, may be reduced to a much poorer condition by cropping than land can be reduced to, that is not limed. It is poſſible to reduce limed land almoſt to a *caput mortuum*; and the better and the oftener the land is ploughed, this is done the ſooner.

The other opinion is ſupported by obſerving, that, in ſome places, lime is applied regularly once in four or five years; that the land ſeldom gets any other manure; that it is kept almoſt conſtantly in tillage; and, with the aſſiſtance of fallowing, carries very good crops.

From theſe obſervations, one is led to conclude, that lime acts both ways; not only makes land exert itſelf in the nouriſhment of vegetables, but alſo enriches it, and adds to the vegetable food.

An inquiry into the qualities of lime will probably illuſtrate this.

Chemiſts tell us, that lime has the following qualities.

It is a great diſſolver of all animal and vegetable ſubſtance: it is a very heavy body: it is an attracter of acids; with theſe it raiſes a fermentation, and produces ſalt; and it communicates its virtues to water.

When theſe things are conſidered, it will appear, that lime promotes vegetation in theſe ways following.

It communicates to the ſoil a power of attracting the vegetable food from the air. It attracts the acids from the air and ſoil; theſe it converts into a neutral ſalt, by which oils are attracted from the air. This operation of lime is confirmed by the experience of thoſe who uſe it as a manure once in four or five years.

Lime enlarges the vegetable paſture. By its weight it penetrates the ſoil; and, by its fermentation with acids, it ſeparates its particles.

This operation of lime is obvious to every perſon that views with attention any land that is thoroughly limed. It appears ſoft and mellow, and obviouſly in a ſtate of fermentation.

Lime diſſolves the vegetable food, and fits it for entering the roots of plants. It diſſolves all the animal and vegetable ſubſtances which it meets within the ſoil, and converts them to vegetable food: and, by the ſalts which it produces, it diſſolves all oily ſubſtances in the ſoil; and conveys them into the roots of plants. We find from experience, that lime clears land of root-weeds. This it does by its diſſolving power. Root-weeds, when torn up by the plough, have their growth checked, and are for ſome time in a languiſhing condition: if lime is applied to their roots while in this ſituation, by its diſſolving power, it is apt to deſtroy them.

That it is owing to the ſalt which lime produces by its attracting and fermenting with acids, that it chiefly owes its power of promoting vegetation, is confirmed by this obſervation. The lime of old walls which has been long expoſed to the air, and where the ſalt is already formed, is much more ſudden in its operations, when laid upon land, than quick-lime.

It has been obſerved, that lime promotes vegetation by communicating to the ſoil a power of attracting the vegetable food from the air, by enlarging the vegetable paſture, and by diſſolving the vegetable food, and fitting it for entering the roots of plants. It is probable, that the two laſt are the ways by which it chiefly operates.

By this it exhauſts the land of its vegetable food. For it cannot be ſuppoſed to attract from the air a ſufficient quantity of food for the nouriſhment of the crops which it enables the land on which it is laid to carry; and it contains none of this food in itſelf. This is confirmed by experience. If land upon which lime has been laid, is exhauſted by crops, the application of lime a ſecond time has not the ſame effect as before; unleſs the vegetable food is ſupplied by dung, or the land allowed to reſt for ſome years, and have the vegetable food ſupplied by the air.

Thus it appears, that lime from its nature muſt act both as a ſtimulus and a manure; while it makes the earth exert itſelf in the nouriſhment of vegetables, in ſome meaſure alſo enriches it, and adds to the vegetable food.

In ſome lands, the diſſolving the vegetable food, and fitting it for entering the roots of plants, may be moſt beneficial: in others, the communicating the power of attracting the vegetable food from the air, may be moſt beneficial. It will not be improper, therefore, to point out how lime is to be applied, that ſo it may chiefly anſwer the one or the other of theſe purpoſes.

In uncultivated land, in which there is a large quantity of vegetable ſubſtance, lime ought to be uſed chiefly as a ſtimulus: and when improved land needs a recruit of vegetable food, it ought chiefly to be uſed as a manure.

When lime is intended for a ſtimulus, a large quantity ſhould be applied at once. For it takes a conſiderable quantity to diſſolve roots, and the other vegetable ſubſtances in the land, and to produce a high degree of fermentation.

When lime is intended for a manure, a ſmall quantity applied at a time is ſufficient. It is probable, that it requires only a ſmall quantity of lime to impregnate a large quantity of earth, and to communicate to it an abſorbent quality, in as high a degree as it is capable of receiving: and it is certain, that it is in proportion to the abſorbent quality which it communicates, that the ſoil is enriched by it. This is not mere conjecture. It is certain, that a ſmall quantity of lime will impregnate a large quantity of water, and communicate to it all its virtues, and theſe in as high a degree too as it is capable of receiving: it is not improbable, that it may operate in the ſame manner upon earth. If a ſmall quantity of lime communicates an abſorbent quality to a large quantity of earth, but has not ſuch influence in diſſolving vegetable ſubſtances, or in producing fermentation, it follows, that the ſmaller the quantity is which is applied, it will operate the more as a manure; and the greater the quantity applied it will operate the more as a ſtimulus.

It is proper to obſerve likewiſe, that when lime is applied in ſmall quantities as a manure, it is neceſſary to repeat the application frequently; for it is probable, that the ſoil by action loſes the abſorbent quality, which the lime communicates.

Theſe things which we have obſerved concerning the operation of lime in ſmaller and larger quantities, are, in ſome meaſure, confirmed by experience. They are agreeable to the practice in thoſe parts where lime is moſt uſed. When barren land is to be improved, it is laid on in large quantities; and when it is applied to land already improved, it is laid on in ſmall quantities, and frequently once in three or four years.

As lime operates by attracting acids from the air, the longer that it lies expoſed to the air before it is ploughed in, it will exert itſelf the more quickly, and with the greater violence. Some alledge, that this ſhould not be done in ſummer. For they ſay, that the ſun acts contrary to the air; as the air ſupplies the ſalt, the ſun exhales it, and communicates it again to the air.

As lime, when laid on in large quantities, exhauſts land of its vegetable food, it is neceſſary to ſupply this food by dung, or ſuch other manures as have it in great plenty; or the land ſhould be managed in ſuch a manner, as to prevent, as much as poſſible, the vegetable food from being exhauſted. Laying off land, after a very few crops of corn, into graſs for paſture, is the moſt proper way of doing this. Land, when paſtured, has not its vegetable food ſo much exhauſted, as when it carries corn. The quantity of vegetable food carried off in fleſh, by the cattle, or conveyed to the air by their perſpiration, bears but a ſmall proportion to the quantity carried off by a crop of corn and ſtraw.

It is neceſſary further to obſerve, that, as lime communicates its virtues to water, land inclining to be wet, and from which the water has free acceſs away, is not proper for it: for the water, in running off, carries along with it the virtues of the lime.

There are a variety of marles, which are commonly reduced to three ſorts: the clay, the ſtone, and the ſhell.

The firſt has its name from its ſimilitude, in appearance, to clay; the ſecond from its hardneſs, and ſimilitude to ſtone; and the third from the ſhells, with which it is mixed, or rather of which it is compounded.

The clay and ſtone marles are of the ſame nature; the ſhell marle is very different from both. This makes it neceſſary to treat of them ſeparately.

Marle of the ſtone and clay kinds promotes vegetation in a ſurpriſing manner. It is probable, however, that it contains in itſelf few of the principles of which the vegetable food is compounded. Plants are not able to find their food in it. When in a bed below the ſurface, it reſiſts the entrance of water, like till or clay. When near the ſurface, and turned up by the plough in great quantities, the ſoil is little better than till, almoſt quite barren. The method of its operation will be beſt known by inquiring into its qualities.

It is obſerved, that both the clay and ſtone marles have the following qualities.

When long expoſed to the air, or put into water, they fall down into a powder: they are very heavy bodies: the earth of which they are compounded, is of the abſorbent kind: they are attractors of acids; with them they raiſe a fermentation, and produce ſalts.

The only difference betwixt them is this: the clay marle is ſooner diſſolved than the ſtone marle; and commonly has a ſtronger power of deſtroying acids, and producing ſalts. Dr. Home ſays, that the clay marle, which he tried, deſtroyed a third more of acids than the ſtone marle.

Theſe marles ſeem to have much the ſame qualities with lime; and, therefore, muſt operate in the ſame manner.

They communicate to the ſoil a power of attracting the vegetable food from the air, they enlarge the vegetable paſture; and they diſſolve the vegetable food that is in the ſoil, and prepare it for entering the roots of plants.

Theſe marles communicate to the ſoil a power of attracting the vegetable food from the air. The abſorbent earth which they contain, and the ſalts which they produce, are ſtrong attractors of oils.

It is obſerved, that they attract oils ſo ſtrongly, that they are uſed by ſome to extract greaſy ſpots from cloaths. When laid upon land, they will therefore attract oil from the air, which is the ingredient of the vegetable food moſt wanted.

Theſe marles enlarge the paſture of plants. They ferment with acids, and fall down into powder, when expoſed to the air, or put into water. Theſe things make them operate in ſeparating the particles of the ſoil, with which they are mixed.

Theſe marles alſo prepare the vegetable food for being nouriſhment to plants. The ſalts which they produce, not only attract oils from the air, but alſo from the ſoil; diſſolve theſe oils, and render them capable of being mixed with water; and of being conveyed by it into the roots of plants.

According to ſome, theſe marles contain ſome oily matter. This, if true, would make them operate in a manner different from lime. But this is uncertain. The earth of which theſe marles are compounded, is of the abſorbent kind; it cannot be long expoſed to the air, without attracting oils; and, therefore, though they contain none in their original compoſition, yet ſome marks of them may appear upon trial.

Theſe marles are long in diſſolving. Large pieces of the ſtone marle are ſeen ſometimes undiſſolved, ſix or ſeven years after it has been laid upon land. This makes it neceſſary to apply a very large quantity of them, otherwiſe their effects will not be known.

As the quantity of marles applied is very great in proportion to the quantity of lime, land, when manured with marle, muſt have a ſtronger power of attracting the vegetable food from the air; and therefore the marle ſhould be preferred, when it can be as eaſily obtained.

As the earth of theſe marles is of the abſorbent kind; as a great quantity of it is applied at one time; and as it is long in diſſolving, it muſt be many years before its operation ceaſes; and, if the land is barren, the nature of it will be changed, and ever after, by the ſame kind of dreſſings it received before, will continue to carry better crops. In this reſpect alſo it is preferable to lime. This advantage, however, depends, in a great meaſure, upon the nature of the ſoil. If the ſoil is ſoft and ſpungy, and has not a firm bottom, the marle, by its weight, will, by degrees, penetrate, like lime, beyond the reach of the plough; and, therefore, muſt leave the ſoil no better than it found it.

Although, in ſome reſpects, theſe marles ſeem preferable to lime, yet we are to conſider, that their principal operation is the ſame with that of lime; which is enlarging the paſture of plants, and fitting the vegetable food for entering their roots. When land, therefore, manured with them, is exhauſted by crops, it cannot receive much benefit from them a ſecond time, if immediately applied. This is confirmed, it is ſaid, by experience. It is obſerved, that marle, when applied a ſecond time to land exhauſted by crops, has not the ſame effect as when firſt applied.

As marle operates in the ſame manner as lime, it follows likewiſe, that limed land exhauſted by crops, can receive little benefit from the application of marle; and that marled land, exhauſted by crops, can receive little benefit from the application of lime. As it exhauſts the vegetable food, the proper manure after it is dung, which contaiint this food in the greateſt plenty.

It was obſerved, that marle operates chiefly by attracting oils and acids from the air; the longer, therefore, that it lies upon land, expoſed to the influence of the air, the more quickly it will operate.

The difference betwixt the clay and ſtone marles was ſaid to conſiſt in this: that the clay marle diſſolves ſooner, and has a ſtronger power to deſtroy acids and produce ſalts. This kind is therefore preferable, as a leſs quantity will produce the ſame effects. If Dr. Home's experiments are to be depended upon, or rather, if all clay and ſtone marles have the ſame powers with thoſe which he made his experiments with, then four cart-load of the clay marle is equal to five of the ſtone.

What was ſaid of lime, with reſpect to the application of it in ſmaller and larger quantities, may likewiſe be ſaid of marle. When barren land is to be improved, the marle ſhould be laid on in large quantities: but when land is in good order, the applying a fifth or ſixth part of the quantity commonly uſed, once in ſix or ſeven years, may have very good effects.

Shell marle is very different in its nature from the other two. It is commonly claſſed among the animal manures.

It does not diſſolve with water, as the other marles do. It ſucks it up, and ſwells with it, like a ſpunge. It is a much ſtronger attractor of acids than they. Dr. Home ſays, that it takes ſix times more of acids to ſaturate it than

any

any of the other marles which he had met with. But the greateſt difference betwixt the ſhell marle and the other marles conſiſts in this. The ſhell marle contains oils. It is uncertain whether the other marles contain any oils; but this kind, it is ſaid, contains them in great plenty.

This marle, it would ſeem, from the qualities which it poſſeſſes, promotes vegetation in all the different ways. It increaſes the food of plants; it communicates to the ſoil a power of attracting this food from the air; it enlarges the paſture of plants; and it prepares the vegetable food for entering their roots.

It increaſes the food of plants by the oils which it contains, and the ſalts which it produces: by theſe ſalts, and by the abſorbent quality which it poſſeſſes, it communicates to the ſoil a power of attracting this food from the air. It enlarges the paſture of plants, by its ſwelling with water, and the fermentation which it occaſions; and it prepares the vegetable food for entering the roots of plants, by the ſalts it produces in fermentation.

It will not be improper to attend the effects of theſe different operations. The communicating vegetable food immediately to the ſoil, and communicating to it a power of attracting this food from the air, have the ſame effects. By both theſe operations the vegetable food is increaſed.

The enlarging the paſture of plants, and fitting the vegetable food for entering their roots, have alſo the ſame effects. By both the vegetable food is diminiſhed. It is obvious, that, by theſe operations, plants are aſſiſted in extracting this food from the ſoil.

The oils which it contains, it is probable, are ſoon exhauſted: having a ſtrong power of attracting acids, and forming ſalts, it is natural to ſuppoſe that theſe ſalts do more than work upon its own oils: they will alſo attract and diſſolve the oils which they meet with in the ſoil; and would exhauſt it of the vegetable food which it contains, was it not for the ſtrong abſorbent quality which it communicates. This quality, it is probable, remains after the operation of the ſalts is over; and thus, upon the whole, the ſoil is rather bettered by it.

We had occaſion to ſhow, that the difference betwixt poor and rich ſoil conſiſteth in the different powers of attraction. As this marle has ſo ſtrong an abſorbent quality, if it is applied in large quantities, and frequently repeated, it is poſſible that it may communicate ſuch an attractive power to the ſoil, as to enrich it in a very high degree, ſo as to need no further manuring, but by proper tillage may be made to attract from the air in the winter ſeaſon ſuch a quantity of vegetable food as is ſufficient to nouriſh a crop in ſummer.

As this kind of marle does not exhauſt land of its vegetable food, as the other marles, or as lime do, it may be applied to land exhauſted by them, or it may be repeated. As it diſſolves ſooner than the other marles, its effects will be more ſudden, and as it does not diſſolve ſo ſoon as dung, its effects will not be ſo ſoon over.

A late author ſuppoſes, that the marle found below moſs is compounded of earth and the alkaline ſalts of rotten wood. He explains in what manner he imagines it is formed. If there is a marle compounded of theſe ingredients, it is different from any of the marles that have been mentioned. However, it will operate much in the ſame manner. It will communicate a power to the ſoil of attracting the vegetable food from the air; it will enlarge the paſture of plants, and it will prepare the vegetable food for entering their roots.

As it contains a large proportion of ſalt, its effects will be ſudden and violent. It is not proper therefore that a great quantity of it ſhould be applied.

As its effects are ſudden and violent, it cannot be expected that they will laſt long. It is probable that they will be ſoon over, after it is entirely diſſolved.

The ſalts which it contains, will make it operate chiefly in diſſolving the vegetable food in the ſoil, and fitting it for entering the roots of plants. By this it will exhauſt the ſoil, if care is not taken to prevent it, by the application of dung, or turning the land from tillage into graſs for paſture.

There is another kind of marle that goes under the name of ſhell marle, and in ſome parts of the country is found in great plenty. It ſeems to be almoſt wholly lime, and it operates in the ſame manner.

Aſhes contain a large proportion of ſalt; they attract acids more violently than any other thing as yet known, but they ſoon loſe their virtue.

The effects of aſhes will then be of the ſame kind with lime. But as aſhes contain ſalt, their operation will be more ſudden; as they attract acids with greater violence, and ſooner loſe their virtue, their operation will be more violent, and ſooner over. This is confirmed by experience. The firſt crop after land is manured with aſhes is commonly very luxuriant, and the ſecond crop exhauſts almoſt the whole of their virtues.

As the effects of aſhes are ſudden and violent, they ſhould be applied in very ſmall quantities; and as they operate in the ſame way with lime, they ſhould not be applied to land exhauſted by lime or marle; ſhould not be followed by theſe, nor repeated.

Turf is compoſed chiefly of vegetables; that which remains then after burning, muſt be of the ſame nature with aſhes. To theſe the fertility communicated to the ſoil is chiefly owing. It is found from experience, that in proportion to the number of roots contained in the turf the burning turns out to advantage; and therefore land, with a tough ſward of graſs upon it, is recommended as the kind moſt proper for being improved in this manner.

The heat which part of the ſoil receives from burning the heaps of turf is ſuppoſed to contribute to its fertility: but this can have little influence except to deſtroy any ſeeds or roots of weeds that may be in the land.

In burning the turf, care muſt be taken to cover the heaps in ſuch a manner as to prevent the fire from breaking out into flame. Where this happens, it is obſerved, that the aſhes loſe part of their virtue, and that the parts of the field manured by them are not ſo much enriched as the other parts are by the heaps of turf that are burned without flame. It is natural to think, that the earth of the turf, when properly piled up, will retain the oils of the vegetables, and prevent them from aſcending into the air in ſmoke and flame.

This makes ſome difference betwixt the manuring by burning and the manuring by aſhes. However, as the oils contained in burned turf are in very ſmall quantities, we may well ſuppoſe that they will ſoon be exhauſted by the ſalts; and therefore, though the effects of burning may be more violent, yet will be equally ſudden, and as ſoon over.

To prevent burnt land from being exhauſted, one crop only, or two at moſt, ſhould be taken, and then turned into graſs for paſture. If a little dung is added after the firſt crop, its fertility will be the longer preſerved.

Soot

Soot cannot be procured in ſuch large quantities as to be uſed by itſelf, excepting in the neighbourhood of large cities; it is needleſs therefore to inſiſt upon it.

It contains oil, ſalt, and earth. Theſe, it ſeems, are compounded in ſuch a manner as to be ready to be conveyed into the roots of plants by water. For the effects of ſoot, when ſpread upon the ſurface, are diſcovered immediately after the firſt rain. It promotes vegetation in the ſame manner as dung, or ſhell marle. It increaſes the food of plants by the ingredients of the vegetable food which it contains. It enlarges the paſture of plants, enables the ſoil to attract the vegetable food from the air, and prepares it for entering the roots of plants by the ſalt that it contains, which is of the alkaline kind, attracts and ferments with acids, and attracts and diſſolves oils.

As it contains great plenty of vegetable food, and as its effects are ſudden, it muſt be laid on in very ſmall quantities. Sowing it in the ſpring on winter corn or graſs, ſeems to be the moſt proper way of uſing it.

When the quantity laid on is but ſmall, and its effects ſudden, it cannot be ſuppoſed to laſt long. Its virtues are commonly exhauſted by one crop.

When its effects are over, the ſoil is left in the ſame ſituation as before it was laid on, not exhauſted of its vegetable food, as by lime or aſhes; and therefore it may be repeated; or it may be followed by theſe manures, as it is very proper to be applied to land that is exhauſted by them.

All the plants that grow upon the rocks within reach of the ſea, are good manures. Thoſe that grow upon the rocks that are almoſt always covered by the water, are the richeſt.

Some kinds of ſea-weed are burnt for kelp. This, it is thought, turns out to greater advantage than uſing them as manures. The beſt kinds for manures cannot be reached, as their roots are almoſt always below water; but they are frequently driven on ſhore by the ſea. A conſiderable quantity of them may always be expected on the ſhore in the neighbourhood of the rocks, where they grow, when a ſpring-tide, heavy rain, and a high ſwelling ſea all happen at the ſame time. The ſpring-tide expoſes their roots to the air, the freſh water falling in rain looſes the roots, and the high ſwelling ſea tears them up. Sometimes the tide carries them to a conſiderable diſtance.

They are of a ſoft pulpy nature, eaſily diſſolve, and ſoon putrefy; and they contain oil, ſalt, and earth. They muſt promote vegetation therefore in the ſame manner as dung or ſoot.

Their effects are ſooner over than thoſe of dung mixed with vegetables from a dunghill; for they ſooner diſſolve and ſooner putrefy.

They may be applied to ſoil in any ſituation, and are very proper for land that is exhauſted by lime or aſhes.

When their effects are over, the land is in no worſe a ſituation than before they were applied, and any kind of manure may be applied after them.

The oftener they are applied, the land becomes the richer; for the earth of which they are compounded, is of the abſorbent kind. This is confirmed by experience. The land near the ſhores, where theſe ſea-weeds are in greateſt plenty, and have been long uſed as manures, are amongſt the richeſt in Scotland, and have been kept almoſt conſtantly in tillage.

They are preferable to dung in this reſpect, that they do not produce ſuch a quantity of weeds. Every perſon that has uſed theſe manures, knows, that weeds do not appear in ſuch plenty upon land manured with ſea-weed, as upon land manured with dung. This ſeems to confirm the opinion of thoſe, who aſſert, that the great quantity of weeds mixed with the dunged land, are produced by ſeeds mixed with the dung. But it is ſubmitted, whether this difference is not owing to the great quantity of ſalts contained in the ſea-weed and applied with it, which at firſt deſtroys ſome of the ſeeds and roots of weeds. Salt, applied in too large a quantity, is undoubtedly a poiſon to many plants. According to Mr. Tull's experiments, a ſmall quantity of ſalt water deſtroyed a plant of mint. It is obſerved likewiſe, when any graſs upon the ſhore is overflowed by a ſpring-tide, it withers away in a few days, and does not recover till it gets a plentiful ſhower. Then indeed, by the freſhneſs of its verdure, it is diſtinguiſhed from the graſs that was not overflowed by the ſalt water. That it is the ſalt in the water that deſtroys the plants, is obvious: for the quantity of freſh water would have had no ſuch effect. And it is probable, that the oils attracted by the ſalts, and carried down by the rain, is the cauſe of their recovery.

In many places, particularly near the ſea-ſhore, broken ſhells are found in beds. Theſe are uſed by ſome as a manure.

They ferment with acids, and, like other animal ſubſtances, contain oil, ſalt, and earth. The oil and ſalt are not in great quantities in proportion to the earth, and they take a long time in diſſolving.

Their operation muſt be of the ſame kind with that of ſhell marle, but ſlower and weaker.

They make ſome addition to the vegetable food by the ingredients of this food of which they are compounded. They communicate to the ſoil a power of attracting this food from the air; and they diſſolve it by the ſalts which they contain and produce. And they increaſe the paſture of plants by their fermentation.

They operate chiefly by enlarging the paſture of plants, and preparing the vegetable food for entering their roots. They are ſo long in diſſolving, that the quantity of oil communicated in a ſeaſon muſt be ſmall in proportion to the ſalts which they produce. Though theſe are their principal operations, yet in them they are inferior to lime, marles, or aſhes.

As they take a long time to diſſolve, and do not operate quickly, it is neceſſary to apply them in large quantities. For without this their operations will ſcarcely be perceptible.

For the ſame reaſon it may be expected they will continue for a conſiderable time. They will continue till the ſhells are wholly diſſolved, and all their oils exhauſted in vegetation.

As they operate chiefly by enlarging the paſture of plants, and fitting the vegetable food for entering their roots; they will in ſome degree exhauſt the land of its vegetable food, though not ſo much as lime or aſhes do, as they communicate ſome oils to it in diſſolving. It is not proper therefore to apply them after lime or aſhes, to repeat them immediately, or apply lime and aſhes after them.

If they are taken up from below the ſurface, as muſt happen moſt commonly, it is proper to allow them to lie ſome time expoſed to the air before they are ploughed down. This will not only aſſiſt their fermentation, but will alſo promote their putrefaction.

As lime, when mixed with them, takes a very ſtrong hand, it is probable, that the mixing them together in the application may in ſome caſes produce very good effects.

It is a practice in ſome places to ſow turnip, buck-wheat, peaſe, &c. on land; and when grown up, to plough them down for manures.

Theſe may be called vegetables in an entire ſtate, to diſtinguiſh them from dung made of putrefied vegetables; though no vegetable can be a manure till it is putrefied.

As theſe vegetable receive their food from the ſoil on which they grow, it is natural to think, that when ploughed down, they do no more than reſtore what they have taken; and therefore, that by this operation land cannot be rendered more fertile than before; at leaſt, cannot communicate ſuch a quantity of vegetable food to it as may be done by frequent ploughings. For the vegetables, though ploughed down, are not all preſerved; a part of them being uncovered, is blown away by the winds. Beſides, the plants while growing cover the ſurface, and prevent the vegetable food in the air from entering the ſoil. Whereas, when land is frequently ploughed, none of its vegetable food is exhauſted, and it is expoſed to receive all the benefits from the influence of the air. But, notwithſtanding this, ſome aſſert from experience, that a crop of ſuch vegetables as thoſe mentioned, ploughed down, render land more fertile than frequent ploughings without the application of manure.

To account for this upon the principles eſtabliſhed, let the following things be conſidered.

The ſoil, manured by ploughing down a crop of vegetables, receives all the vegetable food contained in the ſeed ſown. This quantity in peaſe and buck-wheat is not very inconſiderable. The quantity in one grain is probably as much as there is in a whole ſtalk after the ſeed is fully ripened. It is obſerved, that plants, when cut green, exhauſt land of its vegetable food, but in a very ſmall degree to what they do when allowed to carry ſeed.

Some of the plants mentioned puſh down their roots below the reach of the plough, and bring up the vegetable food lodged there to the ſurface. Peaſe, turnip, clover, and other plants puſh down their roots very far; and whatever vegetable food they find, is ſucked up; and when they are ploughed down, this vegetable food is lodged near the ſurface, and thereby the quantity within the paſture of ſome other plants, ſuch as wheat and barley, is increaſed. A late author makes a calculation of the quantity of vegetable food which clover in this manner communicates to land, and repreſents it as very conſiderable. In few places the ſoil is ſo deep as to have the vegetable food in great plenty beyond the reach of the plough; and therefore it is probable, that this author, in his calculation, makes the quantity of this food brought near the ſurface by clover much greater than it really is. However, it is certain, that as plants puſh down their roots below the reach of the plough, they there find nouriſhment, which is communicated to their ſtems and leaves; and therefore, when theſe are ploughed down, the quantity of vegetable food near the ſurface is increaſed.

The covering of the ſurface ſeems to be an advantage; for thereby the air in the ſoil, not having a free communication with the external air, becomes putrefied, by which a fermentation is raiſed, and the vegetable paſture enlarged. Whatever is the cauſe of this fermentation, the fact itſelf is obvious. Every farmer knows, that when the ſoil has been covered for a conſiderable time by a ſtrong crop of peaſe, or any other kind of corn laid down, and what is commonly called flooming, though naturally hard and ſtiff, becomes mellow, ſoft, and free, and obviouſly in a ſtate of fermentation. It is probable, that this is occaſioned by the corruption of the air, or of the water, which the covering of the ſurface prevents from being exhaled.

To theſe things it may be added, that it is not impoſſible but the plants when growing may ſuck in the vegetable food from the air in as great plenty as the ſoil would have done, though there had been no plants growing upon it. If plants have this faculty, conſidering what an immenſe ſurface is expoſed by them to the influence of the air, the quantity of vegetable food acquired cannot be inconſiderable.

Having thus conſidered the effects of ploughing, harrowing, rolling, and manuring land, in order to produce a large crop of wheat, we ſhall now proceed to the cultivation of the uſeful ſpecies of grain.

It has been very juſtly obſerved by the ancients, as well as moderns, that wheat will grow in almoſt any part of the world, and that, as it is the plant moſt neceſſary to mankind, ſo it is the moſt general, and the moſt fruitful. It thrives not only in temperate climates, but alſo in very hot, and very cold regions; and, when ſown in places where it never grew ſpontaneouſly, ſucceeds as well as where it has been always common. The ſucceſs of our crops of wheat in America plainly prove this: and in Peru and Chili in particular, where this grain was not known till the Europeans introduced it there, it now produces as large crops as in moſt parts of Europe.

Wheat ſhould be ſowed in autumn, and always when the ground is moiſt. In the downs of Hampſhire, Wiltſhire, and Dorſetſhire, farmers begin to ſow their wheat in Auguſt, if any rain has fallen, and even employ their people to ſow one place, whilſt they reap another, if wet weather interrupts them in their harveſt: for if the corn is not forward in autumn, ſo as to cover the ground before winter, it ſeldom does well on thoſe high dry lands, eſpecially if the enſuing ſpring prove likewiſe dry. In low ſtrong lands, ſome huſbandmen think they are in good ſeaſon, if they get their wheat into the ground by the middle of November; nay, it ſometimes is Chriſtmas, or even later, before all their wheat is ſown. But this late ſown wheat, beſides being apt to run too much to ſtraw, eſpecially if the ſpring be moiſt, is liable to be thrown out of the ground by froſts.

In general, all wheat ſucceeds beſt upon ſtrong ſoils, eſpecially if they have been well drained, ſo that the corn lies dry: but as ſome ſorts of this grain thrive better in ſome ſoils than in others, it might redound to the public welfare if more particular obſervations were judiciouſly made, in regard to each kind, than have hitherto been. The white egg-ſhell wheat is reckoned beſt for light lands, and to ſow with rye for meſlin; becauſe it ripens ſooneſt. It ſhould alſo be the earlieſt in the ground. This ſpecies is much ſown in Eſſex, upon their hazely brick-earths, or loams; as the red wheat, and the Poland bearded wheat alſo is there, and in Hertfordſhire upon ſtiff yellow clays. The white Poland, or pole-rivet wheat has not a hollow ſtraw, and therefore is not ſo ſubject to lodge as other corn that has. This kind is particularly fit for lands where the crop is apt to run much to ſtraw.

In

In Oxfordſhire, they have a ſort of wheat which they call long coned-wheat, and reckon the beſt for rank clays. Its ſtraw not being hollow, it is the leſs liable to lodge, and farmers obſerve that it is the leaſt apt to be mildewed, or be eaten by birds, from which laſt it is greatly guarded by its long rough awns; but the flour of it is ſomewhat coarſe. Their white kind of red eared wheat has a white ear and a red grain, and is a very good ſort for clayey land. It yields a good crop, and ſeldom ſmuts.

In Staffordſhire, they reckon the red Lammas or bearded wheat the beſt for cold lands or ſtiff clays.

In Berkſhire is a wheat called pendulum-wheat, from the hanging of its ear, much like the cone-wheat.

In Northamptonſhire, they have a ſort of wheat with a white ſtraw and reddiſh ear and grain; much commended for the plumpneſs and largeneſs of the grain, and the ſtrength of the ſtraw, which prevents its being ſubject to lodge; nor is it apt to be eaten by birds. They have alſo a red eared bearded wheat, and a ſort of pollard or duck-bill wheat, as it is called, known in Suſſex by the name of fuller's wheat, which has ſo cloſe and thick a huſk, that the birds never injure it. Mr. Miller obſerves that this ſort of wheat grows very tall, and, if it be ſown too thick, is very apt to be lodged by rain and wind; for that its ears are large and heavy, and incline on one ſide as the grain increaſes in weight; but that, if its roots are at a proper diſtance from each other, it will tiller greatly and have ſtrong ſtalks, and that the grain of this wheat yields more flour in proportion than that of any other ſort. The awns of this wheat always drop off when the grain is full grown.

Smyrna wheat, commonly called many-eared wheat, becauſe ſeveral leſſer or collateral ears grow around the bottom of the main ear, which is very large in its ſtate of perfection, requires more nouriſhment than the common huſbandry in the large way can give it, and therefore is not cultivated by our farmers: but it would, probably, do extremely well in the horſe-hoeing huſbandry, where the quantity of food can be enlarged almoſt at pleaſure. For the ſame reaſon maiz, commonly called Turky or Indian corn, is fitteſt for this laſt huſbandry. *See* MAIZ.

Some gentlemen have been curious enough to procure their ſeed wheat from Sicily, and it has ſucceeded very well as to the growth: but the grain of this ſpecies has proved too hard for our Engliſh mills to grind.

The beſt time for ſowing wheat is about the beginning of September, eſpecially if any rain has fallen; a circumſtance ſo eſſential, that, if the earth be very dry, the farmer had better ſtay till friendly ſhowers have moiſtened his ſoil, than put his corn in ground where it will not grow before it has been wet, let the time be ever ſo long. Mr. Mortimer ſays he has known wheat to be ſo muſtied and ſpoiled by laying long in the ground, before rain came, that it has never grown at all: to which he adds, that he has likewiſe ſeen very good crops of wheat from ſeeds ſown in July. At all events, the huſbandman ſhould certainly have his wheat ſowing finiſhed by the middle of October. Whoever neglects this, ſhews in ſo doing, a want of proper œconomy in his affairs, and will have cauſe to repent the delay.

Early ſowings require leſs ſeed than late ones, becauſe the plants then riſe better, and acquire ſtrength to reſiſt the winter's cold. More ſeed ſhould always be allowed for poor lands than for rich, becauſe a greater number of plants will periſh on the former. Rich lands, ſowed early, require the leaſt ſeed of any.

Another circumſtance which the huſbandman ſhould carefully attend to in ſowing, is that his eſtimate of ſeed be formed, not from the capacity of any particular meaſure, but from the number of grains which that meaſure will contain; becauſe the grains of ſome growths of wheat are much larger than thoſe from off other lands, though of the ſame ſpecies, and perhaps equally good. By not conſidering this, the ground will of courſe frequently be ſown too thick, or too thin: though I believe farmers are ſeldom apt to run into this laſt extreme. That they too often commit the former error, ſo manifeſtly contrary to their intereſt in every reſpect, is demonſtrated by reaſon, and by daily experience: but neither of theſe is ſufficient to make them deviate from the beaten tract. Inſtead of the uſual allowance of three buſhels of ſeed wheat to an acre of land, repeated trials have ſhewn that half that quantity is generally more than ſufficient: conſequently a great deal of corn is actually thrown away; for the expence of purchaſing ſeed, which moſt ſkilful huſbandmen do, at leaſt every other year, amounts to a conſiderable article in large farms, and in a whole country, merits the attention of the public, eſpecially in ſcarce years: beſides which, the future plants, crowded together by being thus ſown too thick, and not having a ſufficient ſpace allowed them for their ſuſtenance, cannot yield near ſo fine and plentiful a crop as they would otherwiſe produce. A fair trial, made with proper care, would ſoon convince farmers of their error in this reſpect; for if they but examine a field of corn ſown in the common way, they will find few plants with more than two or three ſtalks, unleſs by chance, where ſome of them ſtand ſo as to have room to ſpread. Theſe will have ſix, eight, or ten ſtalks, and frequently many more: but a field of wheat ſown with only a buſhel of good corn has been known to be well covered with healthy vigorous plants, each of which has had from ſix to fourteen, or more, ſtalks, crowned with long well nouriſhed ears, full of fine plump grain, of which it has yielded a much greater quantity than any of the neighbouring grounds ſown with the common allowance. If the land is good, and the plants ſtand at a proper diſtance from each other, few of them will produce leſs than the above number of ſtalks and ears. But farmers think they ſhall have no crop if the ground is not covered with the blades of corn by the ſpring: whereas, if they would have patience to wait till the plants put out all their ſtems, they would be amply convinced of the contrary. Every one muſt have obſerved in places where foot-paths are made through corn fields, that, by the ſide of thoſe paths, where the corn is thin, and has been trodden down in the winter and ſpring, the plants have ſtood erect, when moſt of the corn in the ſame field has been laid flat upon the ground; an advantage which can proceed from no other cauſe, than that their ſtalks are ſtronger from their having more room: for thoſe of the other plants are drawn up tall and ſlender by being too cloſe together.

More ſeed is commonly ſowed upon new broke up ground, than upon that which has been longer in tillage. From half an inch to three inches is the uſual depth at which wheat is planted, according to the nature of the ſoil; the ſtiffeſt lands requiring the ſhalloweſt ſowing, as was before obſerved. The general cuſtom is, to ſow it under furrow, which is certainly moſt adviſeable if the ſoil

be ſhallow, to prevent the plants being thrown out by the winter's froſts, or their roots being left bare by the drying winds in the ſpring. Some ſow in broad caſt, either with a ſingle caſt, or double bout, harrowing once between; after which the ground is again harrowed ſeveral times, till the ſeed is well covered. However, a great deal of it will become the prey of birds, in this manner of ſowing. On the other hand, in planting the corn deep, there is the greater danger of its being eaten off by worms between the grain and the blade.

Great care ſhould be taken to guard againſt the rooks juſt at the time when the wheat is ſhooting up. Theſe miſchievous birds perceive its ſprouting much ſooner than the farmer can, and are led by the ſhoot to pick it up. They muſt therefore be carefully kept off the ground for a week or ten days at this ſeaſon; for at the end of that time the blade will be grown up, and the grain ſo exhauſted of its ſubſtance, that they will not give themſelves any trouble about ſtealing it. They never moleſt the wheat which is ſown about Michaelmas; becauſe ſo much grain of the late harveſt then lies ſcattered about the fields, that they find it eaſier to pick up that, than to ſearch for corn under ground, in the new-ſown lands.

No part of huſbandry requires the farmer's attention more, than keeping his land free from weeds; yet few trouble themſelves much about this eſſential article, are ſenſible of its importance, or underſtand the proper method of doing it: nay, many do not even know which weeds are annual, and which perennial; a diſtinction highly neceſſary to be made by every perſon who would keep his ground clean and in good order, and without which the greateſt induſtry will often be baffled. Annual weeds may be ſoon deſtroyed, if taken in time: but if they are neglected, their ſeeds will ripen, and ſow themſelves in ſuch abundance, that much additional labour and expence will be required to do that which might have been performed with eaſe at the beginning, without ſubjecting the corn to be robbed of its nouriſhment by bad neighbours. The common method of weeding is very abſurd: for in that practice the weeds are to grow till the wheat begins to ear, and they are in flower; by which means, the ground being covered by the corn, all the low weeds are hid, left to ripen, and ſcatter their ſeeds: only the tall weeds are taken out; and if the people employed are not careful, many of theſe will eſcape them, by being ſo intermixed with the ſtalks of the wheat, as not inſtantly to be diſtinguiſhed. At the ſame time great numbers of the plants of wheat are broken and trod under foot by the weeders.

To obviate theſe inconveniencies, Mr. Miller recommends the method now practiſed by good kitchen gardeners, who clear their ground with a ſmall kind of hoe, which, if uſed among the wheat early in the ſpring, before the ground is covered by the blades of corn, will effectually eradicate all the weeds, eſpecially if this work be done in dry weather; becauſe, being ſmall, they then ſoon wither and die. If the ground happens to be very full of weeds, it may be neceſſary to go over it a ſecond time, about a fortnight after the firſt, to cut up thoſe which may have been too ſmall to be noticed. By this means the corn will be kept clean, freed from robbers, which would deprive it of due nouriſhment, and there will not be time for new weeds to grow ſo as afterwards to do it any great prejudice: for the ground will be ſo much ſhaded by the corn, that the weeds will thereby be kept down, in ſuch manner as not to ripen their ſeeds before harveſt.

If, at the time of this operation, ſome of the plants of corn are cut up where they grow too cloſe, the reſt will be greatly benefited thereby: "but in this, adds Mr. Miller, I fear that few of the old farmers will ever agree with me, though what I mention is not from theory, but from experiments, repeated with great care, and ſuch ſucceſs, that the produce of twenty rods of ground was much greater, both in weight and meaſure, than that of the ſame extent in the very beſt part of the field, where this was not practiſed; and the ſtalks of the corn thus thinned ſtood upright, when a great part of the crop in the ſame field was lodged."

Both the advantage of having the plants of corn at proper diſtances from each other, and that of keeping them quite free from weeds, too difficult, not to ſay almoſt impracticable, taſks to be completely effected in the common method of ſowing, are fully obtained in the New Huſbandry, as will ſoon be evidently ſhewn.

M. Duhamel and Mr. Miller juſtly blame the practice of thoſe who either turn hogs in among their wheat, to deſtroy part of it when it grows too thick; or ſheep to eat it down, when they think it too rank. The abſurdity of the former is ſelf-evident: and in regard to the latter, it is well known, from long experience, that the leaves, or blades, of corn are neceſſary to draw in nouriſhment from the air and dews, for the increaſe of the ſtalk and ear. To be thoroughly ſatisfied in this, Mr. Miller cut off the leaves of ſome plants of wheat, alternately, early in the ſpring, and always found the ſtalks of theſe plants much ſmaller, the ears ſhorter, and the grain poorer, than thoſe of the intermediate plants whoſe blades were not cut. Several experiments made by M. Duhamel have proved, not only that all plants are impeded in their growth, and rendered leſs perfect in their productions, but often even killed, by ſtripping them of their leaves: and this is confirmed by Mr. Miller, who adds, that he has frequently obſerved in gardens, that plants diveſted only of their lower leaves, plucked off by ignorant perſons upon a ſuppoſition of their drawing the nouriſhment from the head, have been greatly weakened thereby. The ſame will undoubtedly hold good with reſpect to corn; beſides which, cattle, and particularly ſheep, will often bite ſo cloſe as to deſtroy the crown of the plant, from whence its future growth ſhould proceed.

Wheat is ripe when its ſtraw is turned yellow, its ears hang, no greenneſs appears in the middle of them, and the grain is hard when bitten. From four to five quarters an acre is reckoned a good crop: but ſome would hardly credit how much beyond this the produce of good ground, thoroughly well cultivated, may be increaſed. Thoſe who are ſenſible of the vaſt advantages of a perfect culture, will not be ſurpriſed at Mr. Miller's aſſuring us that he has known eight and ten quarters, and ſometimes more, reaped from an acre, over the whole field, where the corn has ſtood thin upon the ground; and that he has been informed by perſons of great credit, that even twelve quarters have been reaped from an acre of land drilled and managed with the horſe-hoe.

Both wheat and rye may be cut ſomewhat before they are thoroughly ripe, eſpecially if they be lodged; for if the ſtraw be broken, it will no longer convey any nouriſhment to the grain. M. Duhamel ſeems to think this even the moſt eligible way for wheat, becauſe the grain will harden

afterwards.

afterwards in the ſheaf; whereas, if it be let ſtand till it is too ripe, it will ſhed greatly in cutting, binding, and carrying home. It is partly to prevent this inconvenience, that good huſbandmen tie it in the evening, and carry it off early the next morning. The ancients reaped their corn before it was full ripe, as Pliny informs us. And indeed it muſt be allowed that very great diſadvantages neceſſarily attend the letting of ſome ſorts of corn ſtand till their grains have acquired their utmoſt maturity. Both the chaff and the fodder are the worſe for it; and, if ſuch ripe corn takes wet, the increaſe in malt is loſt, if it be barley, it having already ſpent itſelf; and if it be wheat, the quality of the flour is greatly impaired, as well as the quantity conſiderably leſſened. But if corn be cut greeniſh, it will bear a pretty deal of wet without damage; for it will not imbibe the water like full ripe corn, but only take in ſo much as to be kindly fed thereby. Again, if any ſort of corn be blighted, the ſooner it is cut down, though but half ripe, the better it will be; for nouriſhment can no longer be conveyed to it by the ſtraw; but it will be fed by lying in the ear. The ſtraw would become more and more brittle, by ſtanding till the corn is ripe; and the grain comes the clearer from the huſk, when threſhed, if this blighted ſort be cut early.

One man, with a binder, may reap an acre of wheat, and ſomewhat more of rye, in a day, if the corn ſtand well: he will alſo clear about an acre of peas, vetches, &c. in the ſame ſpace of time.

The medium price of wheat, in this country is about five ſhillings the buſhel. If it be much under four ſhillings, the farmer cannot pay his rent and live; and if it exceeds ſix ſhillings, the poor ſort of people cannot afford to purchaſe wheaten bread. A buſhel of wheat weighs from fifty-ſix to ſixty pounds; a buſhel of barley, from forty-four to forty-ſeven pounds; and a buſhel of peas, from ſixty-three to ſixty-ſix pounds.

"The huſbandman, ſays M. Duhamel, cannot have a more favourable ſeaſon to get in his harveſt, than that which is afforded him by hot and dry weather: for the quality of the corn is improved, and the grain is rendered much fitter to keep, by the ſun's having acted powerfully upon it, either towards the latter part of its ſtanding, or juſt after it has been cut: though it is true, on the other hand, that this very circumſtance renders the ears more apt to ſhed their grain, and that the value of a ſowing is often loſt thereby. To prevent this, as much as poſſible, the corn is firſt laid in grips, and then tied up in ſheaves, in the cool of the evening, or early in the morning before the heat comes on; and the mowers of oats frequently work during part of the night, to avoid the exceſſively fatiguing ſultrineſs of the noon. Theſe poor people, whoſe taſk is infinitely laborious, are liable to many grievous diſorders; eſpecially the reapers, who, being obliged to ſtoop to their work, almoſt to the very point where the rays of the ſun are moſt violently reflected by the earth, breathe a perfectly burning air. This forces them to drink copiouſly of liquors, which, being heated by the ſun, allay their thirſt only for a few moments, and, I ſtrongly ſuſpect, often occaſion ſevere illneſſes: the inventing of a machine, engine, or inſtrument, by which the hardneſs of this labour might be mitigated, would therefore be a truly uſeful diſcovery; and I moſt heartily exhort all ingenious perſons who have a mechanic turn, ſeriouſly to think of it.

"The two uſual ways of cutting corn, are either with the ſcythe, or with the ſickle. The former is commonly uſed for oats and barley, or, ſometimes, for very thin, ſhort wheat; and the ſickle is generally appropriated to the reaping of tall and thick wheat and rye. The ſcythe diſpatches ſo much more work than the ſickle, that the difference of expence between reaping an acre, or mowing it, is nearly in proportion of five to two.

"Every part of the mower's body labours and fatigues, and his work requires greater dexterity than that of the reaper: but as the mower is always in a kind of ſtanding poſture, he has the advantage of being refreſhed by every breeze of air; which the reaper, for the reaſons beforementioned, has not.

"I do not deſpair but that ſome engine may, one time or other, be found out, to eaſe theſe very hard labourers, and expedite their work. In the mean while, I am perſuaded that M. de Lille's following account of what he himſelf has practiſed on his own eſtate, will afford ſatisfaction to all my readers, who will be pleaſed to obſerve, that he does not relate matters of mere ſpeculation, but real facts; things actually executed by him, and which I ſhould certainly have tried, if I could poſſibly have been in the country when our harveſts were got in.

M. De Lille's account of his method of mowing wheat.

"When I firſt put a ſcythe into my corn, I was of courſe laughed at by ſome of my neighbours, becauſe they had never ſeen any ſuch thing. I let them enjoy their jokes; but perſevered in my undertaking, which I have now practiſed ſufficiently to be able to point out minutely its advantages, and its inconveniencies; for I allow that, though the former are very great and numerous, it is alſo attended with ſome of the latter.

"The year 1751 was very rainy; our graſs rotted upon the ground, our corn was poor and infeſted with weeds; and the weather continued extremely bad during all the harveſt ſeaſon. One of my fields of wheat, containing about fifteen acres, was, in particular, in ſuch wretched plight, that I did not think the crop worth taking off. However, after walking over it, and viewing it on every ſide, I found that the quantity of graſs and other growths upon it, might, if mowed, afford a great deal of fodder, which would make me ſome amends for the total loſs of my lucerne. I therefore determined to let my horſes have it all, with the little wheat which appeared here and there. This firſt made me think of mowing a field of wheat; tho' I ſoon recollected that I had met with the hint before, in ſome writings. Accordingly, I ſet my mowers to work: my field yielded a great quantity of fodder; the graſs, mowed within two inches of the ground, ſhot up anew, and afforded excellent paſture; and laſtly, my bailiff, more ſaving than I had been, ordered the truſſes to be thraſhed, and got out of them as much wheat as was yielded by other grounds.

"Whilſt I was congratulating myſelf upon the ſucceſs of my operation, by which my horſes and cattle were provided with plenty of fodder for the next winter, I learnt that the huſbandmen in Hainault, Flanders, Artois, and other adjacent parts, never cut their corn down otherwiſe than with a ſcythe; but at the ſame time I was informed, that they do not mow wheat in the ſame manner as oats; that the ſcythes are not made alike for both theſe works, and that there are ſome other eſſential differences.

"Theſe obſervations were a ſort of proof that the practice had been found to anſwer, ſince it was ſtill continued;

and I concluded, that if my operation, imperfect as it was, had ſucceeded ſo well, I might expect far greater advantages when it ſhould be performed regularly: but, not to be too ſtrongly prejudiced in its favour, I reſolved to make a trial upon about thirty acres only.

" By dint of inquiry, I found within a few miles of me a huſbandman who came from the province of Artois, and had been uſed to this very buſineſs. I talked with him; he told me how the work ought to be done, pointed out its advantages, and I retained him for my intended next year's mowing of wheat: but as the ſeaſon was pretty far advanced, and there was not time to procure from his country other people equally well acquainted with the practice, to follow the ſcythe, and do the whole completely in every reſpect, he inſtructed two young lads, as well as he could. In ſhort, nothing was wanting but a mere matter of form, by the neglecting of which ſome of the lifts of the cut corn were miſplaced, ſo that there were ears at both ends of the ſheaf.

" I ought not here to forget the clamour raiſed by this novelty. I made the experiment upon my fineſt wheat; becauſe my new workman had told me, that the ſtronger the corn was, the better and more regularly the mowing would be performed. My neighbouring huſbandmen, and all the reapers employed by them, thought me out of my ſenſes, and ſome of them even came to reaſon the matter with me. They meant well, and I took it kindly; but deſired them carefully to notice the event.

" My experiment was made upon three pieces of wheat, of ten acres each, ſituated in much more extenſive fields of the ſame corn; ſo that there was the faireſt room to make a juſt compariſon between the operation of the ſcythe and that of the ſickle.

" Some of the neighbouring huſbandmen had the curioſity to ſee the work performed, and were ſurpriſed to find that leſs corn was ſhed in this way, than in the common practice of reaping with the ſickle. They thought the method good; but made a few objections to ſome particular circumſtances, in which the experience of ſubſequent years ſhewed them that they were wrong. Their entire approbation then followed; and their mowers, finding that they ſhould be able by this means to cut down all their corn without the aſſiſtance of ſtrolling ſtrangers who often do their work very badly, gladly learnt the new method, and commended it to others.

" This work required a precaution which has been duly attended to ever ſince: it is, to pick all the ſtones from off the land, every year, as carefully as poſſible. The expence of doing ſo is a very trifle, when compared to the advantages attending it. All the roads around my land, which were formerly impaſſable in winter, are now firm and good, fit for any carriage. We no longer hear of horſes lamed, or waggons overturned by them; and, which is equally true, I find that my ground now requires a leſs quantity of ſeed.

" I have now practiſed this method, in an extenſive manner, during five ſucceſſive years, in the courſe of which I have had opportunities of experiencing every circumſtance neceſſary to be conſidered in order to determine its real merit; I mean, mowing in rainy weather, and cutting of corn either bent, laid flat, totally lodged, or lodged only in particular places, and in various directions. I ſhall firſt deſcribe the mechaniſm of this mowing, and then point out its advantages, with the objections of my neighbours, which will ſhew the only inconveniencies I have met with.

" The Flemiſh mowers whom I employed in the year 1753, brought with them ſcythes exactly like ours. I ſaw no ſort of difference in their ſize, make, manner of being mounted, or even in the hooks they were trimmed with; ſo that I found I had been miſinformed by thoſe who told me in 1751, that this work required an inſtrument different from that which is uſed for mowing oats. It was not till the year 1755, that an ingenious workman pointed out ſome very proper alterations, which have ſince been made.

" This intelligent mower obſerved, that the common ſcythe cannot ſuit any ground but ſuch as has been plowed flat; that it therefore was leaſt of all proper for our lands, which are plowed in ridges of ten or twelve furrows, raiſed very high in the midde; and that its hooks broke the ſtraw, plucked off numbers of ears, and did not lay hold of many ſhort plants which grow in the bottom of the furrows, whereby a loſs was occaſioned, or take up the intermixed graſs and weeds ſo exactly as might be wiſhed. To remedy this, he took a ſcythe at leaſt ſix inches ſhorter than thoſe which are commonly uſed, and, inſtead of the hooks, ſubſtituted what he calls the bender, conſiſting of two ſhoots of willow, or other green wood, placed ſemicircularly upon the handle of the ſcythe, where the hooks are commonly ſet. To this end, there muſt be four holes in the handle, ſo that the end of one twig may be put into the lowermoſt hole, and its other end into the third, and the two ends of the other twig into the ſecond and fourth holes. The ſcythe thus trimmed is to be uſed in the manner I ſhall now explain.

" When a mower ſets about cutting down a crop of oats, he places himſelf ſo that the corn is at his right-hand, from whence the action of the ſcythe throws the waving towards his left. The mower of wheat, on the contrary, proceeds from outſide to inſide, ſo that the corn which he is next to cut is always at his left-hand; and that which he has juſt cut, being collected by the bender, is reſted, inclining a little, againſt the adjoining uncut part.

" A helper, which may be a boy of twelve or fifteen years of age, or an elderly woman, follows the mower at the diſtance of four or five feet, with a reaping hook, or a ſtick about a foot and a half or two feet long, and, by putting that through the interval between the ſloping late cut wheat, and the ſtanding corn againſt which it reſts, takes up the former, gives the ſtraw ends a gentle ſtroke or two upon the ground, to form that parcel into a grip, and lays it down at his right hand. This ſhould be done very expeditiouſly, becauſe the picker-up, as this perſon is called, is followed by another mower; and it ſhould alſo be done dexterouſly, becauſe the greater or leſs quantity of gleaning depends thereon. There ſhould be as many pickers-up (we call them binders), as there are mowers.

" The poſture of the mower is a circumſtance of ſuch importance, that I think myſelf happy in having taken particular notice of it in 1754. In cutting graſs and oats, the mower goes in ſuch manner that his feet, which are moved alternately at each ſtroke of the ſcythe, deſcribe two parallel lines. But in the mowing of wheat, the mower's track ſhould be upon a ſingle line, ſo that his right foot, which ſhould be foremoſt, be driven forward by the leſt,

at

at each cut of the ſcythe; not unlike the attitude of a fencer when he advances.

"An accident, which had like to have over-ſet my whole operation in the year 1754, demonſtrated to me the neceſſity of this different poſture. I employed for mowing my wheat, men who uſed to come yearly to cut down my oats: they were ſeven in number. On the third day of their labour, five of them fell ill; upon which I ſet three others to work: but the conſequence was, that I had ten ſick people to take care of at the end of the week. I viſited them, inquired into their ailments, and found, that ſome of them had a fever, but that all complained of violent pains and ſoreneſs under their left ribs. At firſt, I was inclined to think them pleuritic; but, upon a cloſe examination, and upon conſidering the nature of the work they had been at, I ſaw that their illneſs proceeded from badly managed hard labour, the ſtreſs of which had been made to be chiefly upon the left ſide. I therefore ordered them to take their reſt.

"The next day, upon viſiting my infirmary, I found that two of the mowers were returned to their work. I went out to them, and ſaw, even at ſome diſtance, that their poſture in this work was the ſame as if they had been mowing of oats. This immediately ſhewed me the cauſe of their pains. The ſcythes which they then uſed had the common ſort of hooks, and were much heavier than thoſe with only wicker benders. I took up one of them, put myſelf in the poſture of a mower of oats, and ſhewed them, that as a much greater weight reſted upon the hooks of the ſcythe when they mowed wheat, than when they cut oats; it was not poſſible for them, in the poſture they had choſen, to move that increaſed load to the left, without an irkſome twiſting of the body. Then, putting myſelf in the poſture of a fencer, as I had ſeen my Flemiſh mowers do the year before, I demonſtrated to them, that the body was thereby placed in ſuch an attitude as enabled it to exert the greateſt ſtrength, when, by the motion from right to left, it had the greateſt load to ſupport, and that, by the ſame means, this load was carried round without fatiguing the ribs of either ſide. My man took back his ſcythe, tried as I had directed, was convinced of the truth of my demonſtration, taught his companions the ſame method, and they have done their buſineſs eaſily ever ſince. I thought it neceſſary to relate the circumſtances of this accident, becauſe I am ſatisfied that even the ſtrongeſt men would ſink under the labour of mowing wheat, if they were to ſtand in the ſame poſture as the mowers of oats.

"Such is the manner in which this operation ſhould be performed, when the corn ſtands upright, that is to ſay, in the moſt favourable years. I ought to add, that the mower ſhould take care to place himſelf, for his work, in ſuch manner that his left hand may be toward the wind. The corn is then naturally inclined over the ſcythe, and is the more eaſily cut cloſer to the ground. The reſiſtance of the wind, be it ever ſo little, helps to keep the corn which is cut ſteady upon the benders of the ſcythe, and facilitates the motion which reſts it againſt the uncut corn, where the binder takes it.

"The mower is not hindered from mowing cloſe, by the wind's blowing at his back; but the corn which he cuts will not be ſo exactly collected by the bender: ſome of the ears will be a little ſcattered: but the greateſt inconvenience is, that it does not reſt ſo well againſt the ſtanding corn, but is often blown down; which renders the binder's work ſlower, and more troubleſome, and occaſions greater gleanings.

"The wind is in a bad corner for the mower when it blows in his face. It then occaſions a loſs of ſtubble, and a great diſperſion of the ears.

"But the worſt of all winds for this work, is that which blows upon the right hand of the mower. The ſtubble then remains long, and ſo great a quantity of ears lies ſcattered about, that one would hardly think the ground had been harveſted. My mowers did not place themſelves in this manner of their own accord; but I made them do it for a quarter of an hour, to try the effect, of which I am fully convinced.

"When the corn is inclined, or bent, the mower takes it in the direction of its bending, from left to right; which has the ſame effect, in calm weather, as if the wind blew towards his left.

"Corn which is lodged cannot eaſily be mowed inward, becauſe the binder would be inceſſantly impeded by the intangling of his grip with the uncut corn. A good mower judges by his eye, which part, it is moſt proper to begin at, and takes advantage of the wind when it can be of ſervice to him. The method which I have ſeen moſt commonly practiſed, has been by taking the corn in the direction of its bending, and throwing it in waves. The work thus done is neatly performed: no remains of ſtubble are ſeen after the mowing; but the field looks like a meadow.

"Corn laid abſolutely flat, and intangled, is the moſt difficult to cut well. I have ſeen a mower take it in every various direction in which it was beaten down, as if the wind had been conſtantly at his back, and by this means he has cut as cloſe as if it had been only lodged. My wheat was in this condition in the year 1757, and was mowed very regularly: only the work was ſomewhat longer about, than it generally is in other caſes.

"I ſhall not ſpeak of rainy ſeaſons till I come to the objections againſt this method of cutting corn; becauſe they have nothing to do with our mowing, and the only thing requiſite in ſuch caſes is to keep the corn from ſprouting in the ear: but I ſhall here relate the advantage which I find in this practice.

"The preſervation of my fellow creatures is ſo dear to me, that I look upon the means of leſſening their exceſſive hard labour at a time when the heat alone is enough to over-power them, as the firſt and greateſt advantage reſulting from this method. Now I ſee that a good reaper, with his ſickle, can ſcarcely cut an acre of wheat in a day, let him toil ever ſo much; whilſt the mower will diſpatch from an acre and a half to upwards of two acres, according to his ſkill and dexterity. I have, indeed, met with but few able to exceed two acres, when they have done their buſineſs well: but we may reckon that a good mower, taking them one with another, and the corn as it runs, upright, lodged, intangled, &c. will clear an acre and a half, or perhaps an acre and three quarters, in a day, neatly, and without waſting any of it. This mower does then three fifths more work than a reaper can. It is true, he has not the grips to tie up, becauſe the perſon who follows him does that part: but he is obliged to whet his ſcythe when he comes to the end of the field, and ſtill oftener when the corn does not grow thick; beſides which, notwithſtanding all the care that can be taken to clear the ground of ſtones, not a day will paſs without his meeting ſome, which will oblige him to have his ſcythe

new

new hammered; and laſtly, when he has finiſhed a row, he muſt go back to the other end of the field before he can begin another. All this takes up at leaſt as much time as the reaper's binding up what he has cut: and in regard to the hardneſs of the labour on each ſide, I believe that every one who rightly conſiders the nature of their reſpective works, and their poſtures in working, will allow, that the mower's toil and fatigue is three fifths leſs than that of the reaper.

"Another circumſtance, well worth attending to, in this method, is, that the mower is not expoſed to thoſe injuries from thiſtles, thorns, and other noxious plants, which often prove fatal to the reaper.

"From the firſt of theſe advantages reſult ſeveral benefits: 1, A greater riddance of the neceſſary work. Not a year paſſes without the huſbandman's experiencing that ſome part or other of his corn ripens too ſuddenly; and this unexpected maturity, being exceedingly heightened by the leaſt delay, occaſions a great waſte, by the ſhedding of the grain, both when the crop is reaped with the ſickle, and in loading and un-loading it when carried home: whereas the ſcythe, by clearing in two days a field which could not be reaped in leſs than five, in the common way, guards againſt that exceſſive ripeneſs.

"2. This method of cutting down the corn requires fewer workmen.—I muſt here explain myſelf; becauſe the fact would contradict me, if it be objected that a mower and a binder are neceſſary in this way, for what the reaper alone does in the other. But I conſider, that to harveſt ninety acres, for example, of wheat, I muſt employ ten men at leaſt twenty days, with the ſickle; whilſt ſeven mowers, and their binders, (fourteen people), eaſily do my buſineſs in ten days. The difference then is equal to ſixty days work of one man: and if I do not intend to get my harveſt in quicker with the ſcythe than with the ſickle, I take but four mowers and four binders, eight perſons, of which the four laſt ſtand me in leſs expence than three reapers; becauſe I employ for this buſineſs young people, who would not be ſtrong enough to reap with the ſickle. Conſequently I have two workmen the leſs, and ſome advantage in the compariſon between the grown-up man, who has a higher price, and the lad, who anſwers my purpoſe.

"3. The thus employing of children, old women, and men whoſe conſtitution is not robuſt, would be an advantage to the inhabitants of the place. It would afford the means of ſubſiſtance to a greater number of people, and prevent idleneſs and beggary; an important object upon many accounts. Almoſt every pariſh would find within itſelf hands enough to get in it's harveſt, without being obliged to have recourſe to accidental paſſengers, who often work badly, require exorbitant wages, and ſometimes leave their maſter in the middle of the harveſt, if they do not ſubmit to their unconſcionable demands.

"Let us leave ſpeculation, and notice ſome advantages which are evident beyond contradiction. 1, It is not a ſmall one to have a greater quantity of ſtraw, and that ſtraw intermixed with more graſs and other fodder, than when the corn is reaped in the uſual way. This does not need any proof; for every one knows, that the ſcythe cuts as cloſe to the ground as the mower pleaſes. Experience has ſhewn me, that the ſtubble has not been left two inches long upon our mowed fields, where the ſtones had been carefully picked off; whilſt the ſickle generally leaves it eight or nine inches long, and ſometimes much more when the ground is infeſted with thiſtles and other ſtubborn growths, which make the reaper lift up his hand to avoid them. The ſtraw is therefore plainly ſix inches longer when cut with the ſcythe, than with the ſickle; a difference which may be valued at a ſixth part more than that which is uſually reaped in the common way.

"2. The green fodder in the mowed fields ſhoots up anew when cut, and affords excellent paſture after the corn is taken off. The ſame demonſtrative evidence as before, will again take place here with thoſe who but conſider, that the reaper, leaving the ſtubble either eight or nine inches long, takes off only the very tips of the graſs which chances to be within his grip; ſo that, being then near its time of maturity, it ripens its ſeeds, ſows them, and withers away: whereas, when the ſcythe cuts it within two inches of the ground, in its greeneſt and moſt un-ripe part, the yet remaining eyes, and the crowns of the roots, ſend forth new ſhoots, which form a good after-crop for cattle.

"3. The paſture upon fields mowed with the ſcythe, is attended with an advantage, in regard to cows, which may perhaps be peculiar to my country. I know not whether it be the ſame elſewhere. We find every year, and I have always taken particular notice of it, that our cows ceaſe to yield milk during the firſt week of their feeding among the wheat ſtubble. I take the reaſon of this to be, that the ſtubble gets into their noſtrils, pricks them, hinders them from feeding, and makes them range the whole field over in queſt of graſs unattended with this irkſome inconvenience; ſo that they ſpend their time in running about, without grazing. I do not find that this accident happens to cows which are turned in among the ſhort ſtubble left by the ſcythe: the graſs there ſoon ſhoots up a-new, and yields me plenty of paſture, eſpecially if a little rain happens to fall after harveſt.

"It reſults from hence, that the huſbandman is enabled to feed more cattle than he could otherwiſe do, to ſave his ſainfoin or lucerne, and to have a greater quantity of dung; as I have experienced with almoſt incredible ſucceſs.

"I now proceed to the objections, which I ſhall ſtate in the ſame order as they were made; that is to ſay, as each year gave room for one or other of them.

"The firſt was, that the ſcythe muſt make the corn ſhed very much by ſhaking it conſiderably. To affirm the contrary may ſeem paradoxical; though the aſſertion will be proved from manifeſt principles, and by facts. To judge rightly of my propoſition, it will be neceſſary to compare the operation of the ſcythe with that of the ſickle; both of which I have examined very attentively.

"The reaper preſents his hand to the corn, and with wide extended fingers, graſps as much as he poſſibly can; after which, to bring the lower part of the ſtalks ſo cloſe together that the ſickle may encompaſs the whole of his grip, and at the ſame time to give it a tenſion which renders the action of the ſickle more certain, he gives it a violent ſhake, and at that inſtant cuts it. The grip thus cut is generally intangled with the ſtanding corn; or the reaper, when going to lay it down, finds that he has miſſed cutting a ſtalk, or perhaps more, which he then breaks with a jerk of his hand. Thus ſeveral ſhakes precede that which the corn receives afterward when it is tied up.

"The

" The ſcythe has not theſe effects. I have already explained the mechaniſm of its operation, and ſhewn that the corn, cut without any violent ſhake, is carried gently by the bender (or cradle, as we more commonly call it) upon the ſcythe, to the ſtanding corn, againſt which it reſts inclined, till the binder takes it away to tie it up.

" To prove my propoſition by facts, I inſtance the following. After my wheat was mowed in the year 1752, in the manner before related, upon the three ſeveral ſpots of ten acres each, which were parts of much larger fields, I went, with four other perſons, purpoſely to examine with all the care we could, what quantity of grain might have been ſhed by the mowing. We found none at all in the two firſt mowed pieces; but a great deal in the other parts of the ſame fields which had been reaped with the ſickle. In the laſt piece, which was not cut till the corn was riper, we found a little grain in the mowed part, but incomparably more in the other. I did not repeat this ſearch every year with the ſame care, becauſe I had not always the ſame conveniencies of making a compariſon: but I have ſeen enough to be certain that no grain is ſhed unleſs the corn be exceeding ripe, and that much leſs is then loſt by the ſcythe, than by the ſickle.

" The following more important objection was afterward made by a ſenſible huſbandman, who obſerved to me, that, in a rainy year, the corn cut after this manner muſt be more liable to grow in the ear, than that which is reaped in the common way, becauſe the heads of the grips not being ſupported here by a pretty high ſtubble, the wet cannot well drain off; and that the grain will imbibe a great deal of moiſture from the graſs underneath, when the ear is beaten down upon it by rain, which will render it very apt to ſprout as ſoon as the ſun ſhines upon it. I had been told how to guard againſt this accident, but did not try the method till the year 1756, when it anſwered perfectly well.

" This method conſiſts in laying the grips in a triangular form, ſo that the head of one reſts upon the foot of another. This operation is neither long nor fatiguing; nor does it require, in order to do it quick, any thing more than a little dexterity in cloſing the triangle, by making the foot of the third grip ſupport the ears of the firſt. The rains which fell during the harveſt of 1756, rendering the getting in of that year's crops extremely troubleſome, my neighbours had a great deal of ſprouted corn; but mine eſcaped by this method; and what little I had, proceeded from that which remained un-mowed when the rain became inceſſant.

" With regard to the ſheaves, when bound, my Flemiſh mowers informed me, in 1753, of their practice when they are overtaken by laſting rains. It is, to heap upon one another, ends to ends, as many ſheaves as they can poſſibly cover with one, which is then opened and laid over them. My people did not practiſe this method, which I believe the beſt; but they ſecured my corn by other means, which anſwer extremely well, and are generally known.

" From the above objection my huſbandman derived another, relative to the difficulty of drying the graſs and weeds intermixed with the corn, in rainy years, and the danger of houſing the ſheaves when full of that traſh, which may ferment, and be the occaſion of the rotting of a whole pile of wheat. I cannot anſwer this objection otherwiſe than by my experience. The harveſts of 1756 and 1757 were certainly not favoured by the weather: yet all the wild growths which were cut down with, and bound up among my ſheaves, were well withered when they were houſed. No ſort of ſmell which indicated the leaſt fermentation was perceived in any of my barns; the threſhers did not find any thing that looked like it; and the ſtraw which is taken from thoſe barns, to feed my horſes, atteſts that there was not any.

" I now come to the laſt objection; by ſo much the more ſerious, as it is one of thoſe inconveniencies which I cannot remedy, but to which I readily ſubmit. The ears of the corn, ſay the objectors, do not lie ſo even in your grips, as in thoſe which are reaped with the ſickle; ſome of them are in the middle, and others at the very bottom of the ſheaf; ſo that your corn is not threſhed ſo well or ſo regularly, and you thereby loſe perhaps a conſiderable part of it. 2, All the graſs and weeds contained in your ſheaves are threſhed with the wheat, and their ſeeds are mingled with the corn when the threſher meaſures it out: conſequently you pay him for threſhing this traſh, which again increaſes the labour and pay of the winnower.

" All this is true: but let us diſcuſs the matter a little more thoroughly. There are ears in the middle and at the bottom of my ſheaves: but they ſeldom are of any other kind than thoſe which we call backward or late ears; the weak productions of ſickly plants, or of ſeeds not perfectly ſound. Repeated examinations have convinced me, that very few others are in this caſe; and theſe ears hardly part with their grain at any time, in whatever manner they are threſhed; for though the grains be torn from off them by the action of the flail, the inmoſt huſk ſtill adheres to the corn. Theſe diminutive imperfect grains are ſo great a detriment to the fine plump, well nouriſhed corn, that they leſſen its value if not carefully ſeparated by winnowing; after which they ſerve to feed poultry. If theſe ears eſcape the flail, the ſtraw is ſo much the better. Our horſes and other cattle reap therefrom a benefit which we ought not to grudge, becauſe, I think, it turns to our advantage.

" The threſhed graſs and other wild productions, do indeed yield a conſiderable quantity of what are commonly called bad or uſeleſs ſeeds, for the beating out of which I pay the threſher. But the graſs which occaſions this expence, ſaves me that of a great deal of ſainfoin and lucerne which my cattle would conſume: and it would be unjuſt in me to complain of the additional charge in the winnowing, ſince my manager has thought of applying thoſe ſeeds to domeſtic purpoſes, ſuch as feeding fowls, &c. which prove more profitable to me than an equal quantity of the fineſt corn.

" A real increaſe of expence, is what I pay the threſher beyond the common price of the country. This difference, which conſiſts in two-pence or three-pence for a quarter of wheat, is but a juſt compenſation for his extraordinary trouble in unbinding and binding up again perhaps an hundred and fifty ſheaves, and ſometimes more, for what an hundred ſheaves generally yield, when reaped in the common way. But this expence is ſo amply repaid by the extraordinary quantity of ſtraw obtained by my method, that I rate the difference at more than the value of five quarters of corn, which, to ſilence contradiction, I will ſuppoſe to be otherwiſe loſt in my practice. Still my crop is cut down and houſed with far leſs toil and expence, than if it was reaped."

" They begin plowing in the iſle of Thanet, ſays a correſpondent of the editors of the Muſeum Ruſticum, about

about the firſt week in November, contriving ſo that the wheat ſeaſon may be over by the end of the month.

"In the ſpring, if the wheat is rank and the weather dry, they feed it down with their ſheep, which they think makes the wheat branch more, and ſettles the earth about the roots of the plants. Experience has convinced them, that this method of ſowing wheat after trefoil, is better than ſowing it on a fallow; for the land hereabout is naturally very light and hover, and the wheat on that account very much ſubject to be root-fallen. To prevent this, it is no uncommon thing for them, as ſoon as they have ſown their wheat, to drive a flock of ſheep over the land, to ſettle the earth cloſe to the ſeed.

"Their crops of wheat here are generally three, four, and five quarters on an acre; which laſt is, indeed, a very large crop, when it is conſidered, that the land is in general, by nature, poor and barren, and that it is almoſt entirely owing to the induſtry and good huſbandry of the farmers that it is at all brought to bear wheat: in fact, they are an aſſiduous people, and ſpare neither coſt nor labour to improve their land.

"On the light land here they for the moſt part ſow about fourteen pecks on an acre, but on the richer lands they allow four buſhels.

"The farmers here never ſow the ſeed produced by their own land; they find their wheat ſucceed much better by change; for which reaſon the ſeed which they ſow on the light hover-land they chuſe to procure from a gravel or deep cledge, or clay land, taking care that the ſoil on which the ſeed has grown ſhould be as different as poſſible from that on which it is to be ſown.

"Inſtead of making artificial ſteeps with great parade, they make uſe of that which providence has put in their way, wetting their ſeed with ſalt water, which they fetch from the ſea; and they afterwards ſprinkle it with lime, to prevent the ſmut: they are alſo particularly careful to clear their ſeed from wild oats, cockle, &c.

"I know no part of England where there are better farmers; for though they keep their lands conſtantly cropped without fallow, which they call ſowing a round tilth, yet do they ſo manage matters, as to keep them ſtill in good heart.

"They reap their wheat very high here, leaving as much ſtraw as poſſible in the field: this they ſay they do to ſave barn-room. Some farmers here have a practice of ſowing rye to make bands for their ſheaves, the ſtraw being longer, and as they think tougher, than that of wheat. The reaper makes the bands, which he cuts as low as he well can, and binds the ſheaves.

"The wheat ſtubble, which, as I ſaid before, is left very long, is generally mown for the maltſters, as they burn it in their kilns to dry their pale malts for the London market. The greateſt part of this iſland is a light chalky ſoil, ſo that wet ſummers in general agree beſt with it; and it is by this means the farmers here get ſo much money: for when the crops fail in other parts of the kingdom, they are almoſt ſure here to be very large; and they have the great convenience, beſides, of water carriage to the London markets. It is extremely pleaſant, towards the latter end of the ſummer, before harveſt, to ride over this little iſland: I do not imagine there is a more improved ſpot in the kingdom; the fields are all kept ſo clear from weeds, that they reſemble a well kept garden; they grudge no expence in hoeing, weeding, plowing, or manuring; and experience has long ago convinced them, that they purſue a right method. Their practices are many of them good and worthy imitation; it would therefore be great pity if they were not made known, by ſome means or other, to the reſt of the kingdom." *Muſeum Ruſticum*, *vol.* I. *page* 3.

"It is now upwards of ſeven years that I have been tenant of a conſiderable farm in Eſſex; but as there are ſome particular circumſtances attending this farm, I muſt beg leave to ſay a few words on the ſubject.

"The ſoil, which is, for the moſt part, a fine mellow loam, or what is in general called a good wheat ſoil, was in very good heart, and not impoveriſhed; yet the laſt tenant broke on this farm, and the landlord loſt by him near two years rent; for his crops of wheat were continually damaged by ſmut, let him take what care he would of the ſeed, and were beſides often laid, and the land got very foul, though he was not ſparing of his fallows.

"On the contrary, ſince I have occupied this land, it has borne large crops of good ſound wheat, with very little ſmutty corn, and barley, oats, peas, beans, and other things in proportion. What will appear ſtill more ſurpriſing is, that I do not lay on half ſo much dung as he did.

"It will now, perhaps, be neceſſary to explain this ſeeming paradox. At no great diſtance from the farm lives the landlord, who is a man of fortune, and drives a ſet of horſes. This gentleman keeps no land in his own hands, ſo that he was for many years obliged to buy all the ſtraw uſed for the litter of his ſtables, which amounted to a very conſiderable quantity: however, when the laſt tenant of this farm came into it, having been a ſervant in the family, he offered to ſupply the eſquire with ſtraw for his ſtables, provided he might have all the dung, except what the gardener had occaſion for. The 'ſquire thought this a good propoſal, and the farmer imagined he had the beſt of the bargain; ſo the matter was ſoon ſettled.

"Now, you are to underſtand, that the 'ſquire kept, beſides ſeven coach-horſes, a ſtable of hunters, a number of road-horſes, and a pack of hounds; ſo that there was made on his premiſes, in a year, an incredible quantity of rich dung.

"The farmer imagined he was now in a fair way of making his fortune; for his father had taught him, that the man who can command dung is always ſure of large crops: but this did not prove true in the preſent caſe.

"To proceed; my predeceſſor went on ploughing his land, got his fallows in good order, dreſſed them largely with dung, and always ſowed them with wheat.

"His crops of this noble grain, however, by no means anſwered his expectations: his wheat conſtantly looked well and promiſing in the winter and the early part of the ſpring of the year; but as it advanced, it grew rank, and at harveſt was either run all to ſtraw, and was beſides very ſmutty, or elſe, if a heavy ſhower of rain happened to fall, it was lodged, matted, and grew. This was indeed a very mortifying circumſtance, but our farmer could find no remedy for it. He ſeveral times, without ſucceſs, tried folding ſome ſheep on his wheat; but this part of huſbandry, for want of ſkill, he managed ſo badly, that he loſt two entire crops, for he had ſcarcely the return of his ſeed at harveſt. This could never hold long; ſo that in the end he was, as I ſaid before, broke and ruined.

"This man never could be perſuaded that any part of his loſs was to be attributed to the dung he laid on his land, though he conſtantly manured it with the horſe-dung

before

before it was half rotten, and without any mixture to allay its great heat; this kept the ſoil in a conſtant ſtate of fermentation, and ſtocked it with weeds, inſomuch that, when I took poſſeſſion of the farm, ſome of the ſoil was abſolutely mouldy, and ſtunk again, it was ſo rank.

"I will now inform you of my method of management, that you may be enabled to judge how far I was benefited by the errors of my predeceſſor.

"I found ſixty acres of fallow ready for ſowing with wheat: theſe, as the land was rank, I ſowed with the winter tare, which I knew, by experience, would choak the weeds, and abate the rankneſs of the ſoil. In ſome parts, where the ſoil was not ſo rank, I ploughed in the tares in order to ſow wheat over them; in other parts I ſuffered the tares to ſtand for a crop, which, however, was not conſiderable, they ran ſo much to ſtraw or haulm.

"When the tares were off, I got the land inſtantly in order, and ſowed the whole with wheat, of which I had a better and cleaner crop than had been known upon the land for upwards of ſeven years before: this all my neighbours acknowledged: however, it was neither clean enough, nor conſiderable enough, to ſatisfy me. Some of your readers, may perhaps wonder what I did with my tares, as but few are ſold at the country markets; but I muſt inform them, that I live within ten miles of a ſea-port town, whither I ſent them at various times, in order to their being carried by ſea to London.

"I am to obſerve to you, that I continued the agreement of giving the 'ſquire ſtraw for his dung; but I made a uſe of it very different from my predeceſſor.

"I make it a rule never to manure for wheat, or ſow wheat on a fallow. I do not indeed allow many fallows on my land; and when I do, I generally ſow my fallow with barley, to which I allow four or five ploughings. This commonly yields me a large return, and I have a good crop of wheat after it.

"This, however, is not my general method; for I am very fond of the hoeing huſbandry, to practiſe which, in ſome degree, is the only infallible way of keeping land clean. To begin then with my method, I never lay dung alone on my land, let it be ever ſo rotten; but as ſoon as I get any long dung from the 'ſquire's, I carry it to my compoſt-heap, where it is mixed in alternate layers or beds, with freſh virgin earth, (if I can get it) lime, or chalk, lime rubbiſh, ſcourings of ditches and ponds, turf, leaves of trees, and all the dung and offal of my family, of the hog-yard, the poultry-yard, and the dog-kennel. As to my pigeons-dung, I always preſerve it to mix with ſoot, and uſe the mixture as a top dreſſing for my wheat, whenever it happens to be too backward in the ſpring.

"But to return to my compoſt: I have always ſeveral diſtinct heaps of differentages, and I ſometimes leave it three years before I uſe it, and never lay on any under two years old.

"When I have got a plot of ground in order, I give it a thorough good dreſſing of this compoſt, which I immediately plough in. I then ſow it with ſome crop that requires hoeing, ſuch as horſe-beans, broad-beans, or white or grey peas. During the whole ſummer, I take care to keep theſe crops very clean by hoeing, eſpecially if the ſeaſon is rainy; and I am particularly cautious in preventing any of the weeds from perfecting their ſeeds.

"When my hoeing-crop, which generally more than pays me all my expences, is off the land, I immediately get it into as fine tilth as I poſſibly can, by repeated ploughings, and then ſow it with either wheat or barley, whichever is likely to pay me beſt; for little as ſome of your readers may think of it, barley, when it is ſown on good land well prepared, is very frequently as profitable a crop as wheat.

"By thus ſowing my wheat after a hoeing-crop with dung, I have always a good return of clean corn, often five quarters on an acre; and my land will ſtill be in heart enough to give me a reaſonable crop of oats; after which, without any fallow, comes my hoeing-crop, &c.

"When I ſow barley after the hoeing-crop, I ſuffer wheat to follow it; and then it is that, if I find it neceſſary, I give the wheat in the ſpring a top-dreſſing of ſoot mixed with pigeons-dung.

"I ſometimes allow only ſix pecks of wheat-ſeed to an acre: this is when I ſow over it, in the ſpring of the year, eighteen pounds of broad clover-ſeed, which I harrow in with a pair of very light harrows; and it does not in the leaſt damage my wheat-plants. I leave the clover only two years on the land; for the ſecond year, after I have mown the firſt crop for hay, I ſuffer the ſecond to grow very rank, (having given my land a ſlight dreſſing upon my compoſt dung-hill the preceding year) which I plough in, and over it ſow wheat, to be harrowed in on once ploughing.

"Theſe crops of wheat are ſmaller in quantity than any others I get, but the grain is finer, plumper, brighter, and heavier, generally ſelling for more at market, as being always very clean and clear from ſeeds of weeds.

"In my method of farming, ſome particulars are to be noted. In the firſt place, as my crops ſucceed one the other very quick, I am under a neceſſity of having all my ſtubble extirpated before I give the land the firſt ploughing after the crop is off. If it is a wheat or bean-ſtubble, I generally have it all pulled up by hand by women and children; barley and oat-ſtubbles I have torn up by a pair of loaded drags, and afterwards gathered into heaps and carted to the compoſt-heap. This I do to prevent the ſtubble from being buried by the plough, and from growing mouldy in the land; from which mouldineſs I have great reaſon to think ſmut often proceeds.

"Another thing to be noted is, that I allow leſs ſeed to my land than moſt of my neighbours, my quantity being from ſeven to nine pecks of wheat, from nine to twelve of barley, and about twelve of oats to an acre of land; but it is always to be preſumed that the ſeed I ſow is good. If any farmer ſhould imagine that theſe quantities are too ſmall, let him ſuppoſe every wheat-plant to occupy a ſpace of ſix inches ſquare, which is ſmall enough: let him then calculate how many ſuch ſpaces there are in a ſquare acre. When he has done this, let him proceed to count how many grains of wheat there are in a pint, which multiply by the number of pints in nine pecks, and he will find by the reſult that I, in fact, allow too much ſeed." *Muſeum Ruſticum, vol.* V. *p.* 104.

"I have, for ſome years laſt paſt, held a conſiderable farm in the county of Leiceſter, and have, thank God, met with ſome ſucceſs in my practice.

"My methods of farming are thought by many to have ſomething peculiar in them; yet, as I do not often miſcarry, no one has a right to find fault with me.

"Great part of my farm is very good wheat land, the ſoil being a ſubſtantial loam.

" I frequently, as well as the reſt of my neighbours, make uſe of lime as manure; but then I uſe it differently from what they do.

" The common practice is, to lay about forty buſhels of unſlaked lime on an acre, which makes a peck on every ſquare perch, (half a buſhel when it is ſlaked.) On wheat land they ſpread the lime at the ſame time they ſow the ſeed; but this is a way I do not much approve, and for this reaſon I vary my practice. The method I uſe is as follows: I ſow my wheat without laying on any manure; but in the biginning of the month of February I get, for every acre of land I intend to lime, twenty buſhels of that manure, unſlaked, and forty buſhels of ſand, or the rubbiſh of a brick-kiln.

" Towards the latter end of the month I cauſe the lime to be ſlaked, which doubles its meaſure, and very well mixed with the ſand; immediately after which, in the laſt week of the month, I have it ſcattered by way of top-dreſſing over the green wheat; and as rain generally ſucceeds, it is ſoon waſhed down to the roots of the plants, and gives them a vigour and ſtrength of growth, that is really aſtoniſhing to a perſon who had never ſeen this method practiſed.

" This is my way, if I ſee the weather is inclinable to be wet; but if it is dry, and not likely to rain, I double the quantity of ſand, in order to take away all danger of the wheat-plants being burnt, or hurt, by the ſtrongly-corroſive power of the lime.

" The above method I would willingly recommend to the attention of your readers; and though I have benefited greatly by it, yet need they not take my word, as it is ſo very eaſy to make a ſmall trial, and form a judgment from the ſucceſs they may have.

" I muſt obſerve, that I look upon it to be almoſt a matter of indifference what kind of ſand I uſe, except that I prefer lime-ſtone ſand to the cryſtal ſand, as being moſt abſorbent, and in truth prefer the rubbiſh of broken bricks to either.

" It will perhaps be unneceſſary to tell your readers my motive for this preference; yet that I may not be thought obſcure, I ſhall do it.

" When lime is ſlaked, it crumbles and falls into very minute particles: the ſmalleſt of theſe particles are, together with the moiſture that adheres to them, abſorbed by the large open pores of the brick-rubbiſh, which afterwards diſpenſes them by ſlow degrees to the ſoil on which it is laid, for the ſupport of the crop: this occaſions the operation of the lime to be more equal; the parts which were not abſorbed, are firſt attracted by the earth; theſe nouriſh the young plants, which, in time growing ſtronger, have power to draw from the abſorbent the particles it had reſerved for their uſe." *Muſeum Ruſticum*, *vol.* III. *p.* 366.

" Almoſt every part of this kingdom has a method of farming peculiar to itſelf; and this I have often found to be true, in the many journeys I have made through various parts of the iſland.

" A ſhort time ſince, my occaſions calling me down into the Weſt, I ſtopped for a few days in Wiltſhire, where I could not help obſerving, that the wheat-corn was remarkably backward, though it, in general, promiſed to be a good crop.

" I thought it worth my while to aſk ſome of the neighbouring farmers the reaſon of this appearance, when I was informed that moſt of the wheat was ſown late, owing to a wet autumn, which prevented them from giving their land the neceſſary ploughing for that crop ſooner than November, December, and even January.

" The ſoil is a pretty good loam, on a chalky bottom: and I found they often ſow late; but whenever they do it, they take care to allow an additional quantity of ſeed, generally one fourth, or a third, more than they uſe when they ſow early.

" I was alſo told, that many benefits often reſulted from ſuch late ſowing; particularly, the crop is generally clearer from weeds; for in early-ſown wheat, poppies, and other noxious weeds, are very apt to get a-head, and injure the corn. I even ſaw in my walks many early-ſown fields, which rather ſeemed to be under poppies than wheat, as the poppies were in full bloom, and made a glaring appearance.

" The Wiltſhire farmers, the beſt of them I mean, often give their land four ploughings for wheat; and they find their advantage, as it is by ſuch means brought to a fine tilth, and yields a good crop.

" Another advantage they told me they had from ſowing their wheat late was, that in the blooming ſeaſon the weather was generally fine; whereas, in a wet ſummer, the bloom is often waſhed off from the forward-ſown wheat.

" But it muſt not be imagined this method of ſowing wheat late is indiſcriminately purſued: in many circumſtances it would be very imprudent to do it.

" This method of huſbandry muſt, to meet with ſucceſs, be chiefly practiſed on fallows, where the land is good, and has been well dreſſed.

" Every crop, and method, has dangers to encounter; and the chief danger of late ſowing is, that a froſt may come on juſt as the ſeed begins to ſprout; but then good land, well dreſſed, is not ſo ſubject to this misfortune as poor, unmanured land, that has, perhaps, been not half ploughed.

" I find, from enquiry, alſo, that it is dangerous ſowing wheat on clover lays on one ploughing only, unleſs it is done ſooner than the middle of November; for the turf, or graſs lay, forms a cruſt immediately under the ſeed corn, and this not only prevents its taking a firm rooting, but alſo expoſes it to the ravages of field fowls, which are, at this ſeaſon, particularly voracious, as having a ſcarcity of food; and the infant plant is, beſides, liable to be killed by the froſt, juſt as it is about ſprouting and ſhooting out its firſt leaf. It ſtands, therefore, to reaſon, and is warranted by experience, that wheat ſhould not be harrowed in on a clover lay, on one ploughing, ſo late after the middle of November, as the danger is great, though the loſs may not always be certain." *Muſeum Ruſticum*, *vol.* III. *p.* 1.

" As I have been many years a farmer, it is not to be wondered at that I ſhould know ſomething of huſbandry.

" Experience, which is an excellent miſtreſs, has, in fact, beſtowed on me moſt of the knowledge I have acquired: I imagine, therefore, that an account of the reſult of this experience, will not be unexceptable to your readers.

" Moſt farmers chuſe to ſow wheat on a fallow; we, in Eſſex, on the contrary, often, not without good reaſon, avoid it. Every fallow deſigned for wheat requires a good dreſſing of rotten dung, or ſome other manure; and this dreſſing, we imagine, often is the cauſe of a ſmutty crop, if laid on uncompounded; therefore, whenever I ſow my wheat on a fallow, inſtead of laying on my muck-heap unmixed, I make it into a compoſt in the preceding ſpring:

this

this compoſt conſiſts, according to the nature of the ſoil it is to be laid on, either of chalk, light earth, and rotten dung, or of lime, clay, and dung, laid in a heap, in alternate layers, or beds.

"This compoſt-heap I cauſe to be frequently turned during the courſe of the ſummer, till it is thoroughly mixed, and forms one united maſs of manure, rather crumbly than otherways.

"With this manure I dreſs my fallows in the ſame manner farmers lay on their rotten dung alone; and I find, by experience, it is leſs apt to heat and canker the wheat-ſeed, and it is alſo much leſs inclined to mould and burn the ſeed.

"This, I ſay, is my method of management when I ſow my fallows with wheat as a firſt crop; but I more generally approve of making wheat the ſecond crop after barley, oats, beans, or peas.

"I am ſenſible many of your readers will be ſurpriſed at this method, and exclaim that it is impoſſible to get a good crop of wheat but after a good fallow; yet I know the contrary: it is from experience I know it; may I not therefore venture to aſſert it?

"When I intend to ſow wheat as a ſecond crop, I lay my due quantity of compoſt on the land ſome time before I ſow it with barley, oats, beans, or peas.

"When this crop is off, the following year I ſow wheat. You may ſuppoſe the land to be duly prepared by well-timed and careful ploughings; but I am to premiſe, that after beans and peas, being hoeing crops, the land is much ſooner brought into good tilth, than after oats or barley.

"The wheat ſowed the ſecond year of the fallow is, with me, generally a good crop, and almoſt always clear from ſmut and pepper-wheat.

"If, by any accident, the wheat ſhould be ſickly, or pining, after Chriſtmas, I beſtow on it a top-dreſſing of wood aſhes, ſoot, if I can get it, or coal aſhes, if the ſoil happens to be ſtrong: this ſeldom fails anſwering my expectations; checking the growth of the weeds, and forwarding that of the corn.

"It is very frequently that I ſow wheat in this manner for a ſecond crop; but when I have an opportunity of chuſing, which I cannot always do, as I muſt ſuit my crop to my wants, I preſer, for the firſt crop, beans or peas, either of which I take to do the land nearly as much good as a fallow.

"Neither peas, nor beans, are, in my opinion, great impoveriſhers; and the frequent hoeing which they both require, if they are properly cultivated during their growth, brings the land into finer order than the beſt regulated courſe of huſbandry with the common implements could effect.

"Wheat ſucceeds particularly well after either of theſe two laſt-mentioned crops; and, I have found, by experience, that if peas, or beans, are made intermediate crops, and are well and properly hoed during their growth, land of a moderate quality may, without being impoveriſhed or hurt, be made to bear a continued ſucceſſion of crops for many years; but it muſt be underſtood that it ſhould, from time to time, be refreſhed with proper dreſſings of well-prepared compoſt.

"I know, many farmers think there is no ſuch thing as carrying on a courſe of huſbandry without allowing, once in three or four years, a year of fallow; but ſuch are little acquainted with the benefit reſulting from hoeing crops; and it is this benefit that has of late induced farmers to ſow ſuch immenſe quantities of turnips in the counties of Norfolk, Suffolk, Eſſex, and other counties adjacent.

"Many of the advocates for intermediate fallows think that the earth requires reſt; but this is a great miſtake; for I could eaſily make it appear that, in a proper method of huſbandry, land might be almoſt continually cropped, without being impoveriſhed or worn out.

"The real benefit accruing from frequent fallows is, that they allow the huſbandman time and opportunity to bring, by good tillage, his land into proper order for the reception of the ſeed; but in the method of huſbandry I would recommend, the land would always be kept, by frequent ſtirring, in ſuch good tilth, that the time betwixt gathering the crops, and ſowing the next ſucceeding ſeed, would be abundantly ſufficient for any preparation it might require; for it is a well-known fact among huſbandmen, that when land is well tilled and kept in good order, one ploughing will go much farther than three where the land has been neglected, is rough, and grown hard and cloddy, through inattention or lazineſs." *Muſeum Ruſticum, vol.* III. *p.* 3.

"A wet harveſt, ſays an old huſbandman, is what a farmer dreads more than almoſt any thing, as it hurts the quality of his corn, increaſes his expences, and greatly leſſens his profits.

"So much depends on the well getting-in of our bread-corn, that every man, who knows any thing that can forward ſo good a purpoſe, is, I think, in duty bound to communicate it for the benefit of the public.

"It is a well-known maxim that wheat ſhould be left for ſome days in the field, after it is cut, before it is inned: this, the farmers think, and not without reaſon, improves its quality; the dews plump the kernels, and the ſun brings it to a proper and perfect ſtate of maturity.

"Theſe then are the benefits that reſult from leaving the ſheaves for ſome time abroad; but it is neceſſary the weather ſhould be fine, or great loſſes are often the conſequence of this practice.

"Sometimes, when the farmer leaſt expects it, the weather ſets in foul, and it rains for ſeveral weeks ſucceſſively: it is then very difficult to preſerve the wheat from being greatly damaged, notwithſtanding the many contrivances that have been thought of for this purpoſe.

"Some ſhock their ſheaves, ſetting them up in traves of ſix ſheaves of a ſide, and two to cap them; but this is a very dangerous method, and never to be practiſed after much rain has fallen: if the ſheaves were dry when the traves were ſet up, from an expectation of its raining, it is of great ſervice; but if the ſheaves are firſt ſuffered to be wet, ten to one but the corn ſweats, ſprouts, and rots, by being ſo cloſe confined from the action of the air.

"After all, I am apt to think that it is full as well not to cap the ſhocks; for if the rain is not very heavy and conſtant indeed, the ears, provided they do not touch the ground, will dry nearly as faſt as they are wetted.

"In Middleſex, Kent, and ſome parts of Eſſex, they generally bind their wheat as they reap; but then it muſt be ſuppoſed that their crops are, for the moſt part, pretty clear from green weeds, which would otherwiſe cauſe the ſheaves to ſweat violently in the mow, and greatly damage the corn.

"When a farmer is ſo unfortunate as to have his wheat-ſheaves thoroughly wetted, if fine weather enſues, I would by all means adviſe him to unbind them, and afterwards

ſpread them out to be dried by the ſun. This ſimple method will often prevent great loſſes, and the wheat may at laſt be got in in tolerable good order.

"If the rain, however, ſhould continue long, and there ſhould be danger of the kernels growing, which by obſervation he may eaſily judge of, I would adviſe the thinking farmer inſtantly to carry it home wet as it is, and afterwards manage it as I ſhall direct from my own frequent experience.

"When the waggon, or cart, comes home loaded with ſheaves, let them be thrown promiſcuouſly into the bay of the barn, and not regularly moved; for it is neceſſary they ſhould lie hollow, that the air may get into the vacuities, and prevent the ſheaves from heating during the little time they are to continue in the ſituation above deſcribed.

"Let our farmer next prepare ſome cutting-boxes, ſuch as horſe-meat is cut in, in Kent, and ſome other counties. The number of theſe boxes ſhould be according to the quantity of wheat he has wet; but three or four conſtantly kept going will do a great deal of work.

"With theſe cutters let the ears be cut off from the wet ſheaves; and when a ſufficient quantity are collected from all the boxes, let them be put looſely up in ſacks, and carried to a malt-kiln, there to be regularly and gradually dried; and when the firſt parcel is done, another is to ſucceed, and ſo on till the whole work is completed.

"This method I can, from my own experience, recommend to your readers; and it is leſs expence than would at firſt thought be imagined. The heat of the kiln may be kept up higher than when malt is drying, as the chaff of the ear will prevent the kernel of the wheat from being damaged by the fire, unleſs the heat is very intenſe indeed; but it will, however, be proper to keep the ears gently ſtirring with a fork, or rake, during the time they are drying.

"In this management the farmer will find great advantages; and his wheat will, with a very inconſiderable addional expence, be nearly, and ſometimes quite, as good in a wet harveſt, as if it was houſed in ever ſo good order, in fine ſun-ſhining weather.

"If, by chance, after you have cut off the ears from the ſheaves, the weather ſhould change, and become fine, you may often dry them without the aſſiſtance of the kiln, by ſpreading them thin on a large threſhing-cloth, and turning them frequently with a wooden rake; and even, if by this method you ſhould not entirely dry them, it will ſtill bring them ſo forward that the kiln will eaſily complete the cure.

"I muſt, however, before I conclude, caution the farmer not to ſuffer the kiln to be much heated, unleſs the ears are kept conſtantly ſtirring during the time they are drying." *Muſeum Ruſticum*, *vol.* II. *p.* 106.

"Give me leave, ſays a practical farmer of Warwickſhire, to mention to you a practice which, however, I do not abſolutely recommend, though with me it ſucceeded, and, as I have been informed, has done ſo with ſeveral other farmers, who have ventured to make the experiment.

"A few years ago, after what I thought a good fallow, I ſowed a field, containing five acres, with wheat. The ſoil was a good loam, but rather light than ſtiff, and inclined to be ſtoney. The wheat plants looked healthy during the whole winter, and promiſed fair to yield me a plentiful crop; but in the ſpring, warm rains coming on brought ſuch ſtore of weeds, that my wheat was in danger of being choaked.

"I was for ſome time puzzled what to do; for it being now the latter end of May, and the wheat being on the ſpindle, and ſome even in the ear, to weed it with hooks would have been endleſs, not to mention the damage that would have been done to the plants by the weeders feet.

"I had at one time thoughts of mowing wheat and weeds all together, and drying them to make fodder for my cattle: intending, if I had done this, to have got the land as faſt as poſſible in order, and ſown it again with wheat the ſucceeding autumn.

"However, in looking over the field, I found no great deficiency of wheat plants; but they were in moſt places ſo over-topped by the weeds, as to be ſcarcely viſible, and in the furrows, in particular, not a blade of wheat was to be ſeen.

"My method of ploughing for wheat-ſeed in this land is, to make narrow ſtitches, but wider than a ridge, and more rounding, being not ſo ſharp on the back.

"Whilſt I was meditating what to do in this matter, a gap was by ſome accident made in the hedge, and a parcel of my ſheep got into the wheat field.

"As ſoon as I ſaw where they were, apprehending great damage, I ordered them to be immediately driven out, and the gap mended.

"On taking a ſurvey, I was not a little ſurpriſed to find that the ſheep, inſtead of doing any damage to the wheat, had done it a great deal of good, for they had eat up almoſt every weed which grew in that part of the field next to the paſture.

"Encouraged by this accidental diſcovery of a propenſity in ſheep to eat weeds rather than wheat, I turned a hundred of my flock, into the field, two or three hours in the morning and the evening, for ſeveral days together, till all the weeds were nearly conſumed.

"On inſpecting my field afterwards, I found the ſheep had done very inconſiderable damage to the wheat, but the weeds were eat down ſo cloſe that they could never again get a-head; the wheat going on proſperouſly, and yielding me at harveſt a plentiful crop of clean, good corn, which was more than any of my neighbours could that year boaſt of.

"Whilſt the ſheep were eating the weeds, I found they moſtly walked in the furrows, as being eaſier to their tread than the ſloping ſides of the narrow ſtitches; and this might be one reaſon of their doing the wheat ſo little damage by their treading.

"In this new method of huſbandry I took, however, one precaution, which, I am apt to think, greatly contributed to my ſucceſs.

"The precaution, I mean is, that I never let them lie in the fields at night, as the weight of their bodies when they lay down to ſleep could not have failed doing great damage to the plants." *Muſeum Ruſticum*, *vol.* III. *p.* 31.

"Permit me, ſays another experienced farmer, to communicate to your readers, for their benefit, I hope, a little of the experience I have in many years acquired.

"Being now grown old, and retired to ſpend the remainder of my days in this city, I trouble myſelf but little about the practical part of farming; yet did I ſome years ago occupy a conſiderable tract of ground in Norfolk.

"I ſhall, for this time, confine myſelf to the propriety and impropriety of feeding wheat down with ſheep in the ſpring;

ſpring; a practice which has by many been hitherto but little underſtood.

"This practice, when prudently adopted, is replete with many and great advantages; but if indiſcriminately adopted, nothing would ſooner ruin a farmer.

"The advantages to be derived from it are, that it affords feed for your weathers and ewes after the turnips are conſumed, and before the ſpring feed comes in; it cauſes the wheat to tiller and branch more than it would otherwiſe have done, and of courſe produce a larger and better crop; it brings, by the rich manure it affords the land, the crop forwarder, and makes it heavier in the ſcale, as well as plumper in the buſhel.

"The diſadvantages attending this practice are, that, in certain circumſtances, it checks the growth of the corn, and makes the ſecond ſhoot diminutive and ſmall; of courſe the ears are lean and poor, and the crop in proportion. It gives the weeds an opportunity of getting ahead, and ruining the crop, to the farmer's great loſs and diſappointment.

"I ſhall, to be better underſtood, relate ſome caſes which happened to myſelf, as I find them noted in my journal, for I always kept one.

"In the year 1742, I had ten acres of wheat, which, after Chriſtmas, ſeemed proud. The ſoil was a looſe loam, and I had, when I fallowed, laid on plenty of dung.

"I turned into this field a parcel of ſheep on the twenty-ſecond of January, in order to feed it down, which they did; but the weather coming in milder than I expected, the weeds, which had been brought in with the dung, got ſuch a head, that I was above twenty pounds loſer by feeding it.

"In 1744, I fed, very indiſcreetly indeed, another piece of wheat of fifteen acres. The land was poor, and had not been well dreſſed, ſo that about the tenth of March the wheat-plants ſtood very thin. I turned in ſome ſheep, thinking it would afterwards branch more, and produce a better crop; but I was diſappointed, for the ſheep bit off the knot of the plant, and I had, I think, the worſt crop I ever reaped.

"The next year, 1745, I had another thin crop of wheat on much the ſame land as the laſt: I turned in ſome ſheep the ſixth of February, before the knot was above the ground within reach, and it ſucceeded; for, as I gave it a good top-dreſſing within a fortnight, it tillered and branched ſo well, as to produce a much better crop than I expected.

"I could relate to you many other circumſtances of this nature, but it would take up too much room; I ſhall therefore proceed to make ſome obſervations on my general experience in this matter.

"I find wheat ſhould never have any ſheep turned on it, unleſs it is forward in January, and likely to be lodged at harveſt, except now and then, with great precaution, when you want to thicken a crop.

"Such wheat only ſhould be fed down as was early ſown; and I hold it a bad practice if the land is rich with dung.

"Wheat ſhould not be fed down, unleſs the land is pretty clear of weeds, and has ſtrength and ſubſtance enough to afford the wheat nouriſhment in plenty, that it may get into ear at the proper ſeaſon, notwithſtanding the growth was ſo checked.

"There is in every plant of wheat a certain knot, or crown of the root as I call it, from which all the branches iſſue: now, if this crown is nipped off by the ſheep, a dwindled production is the certain conſequence; for this reaſon, ſheep ſhould never, (unleſs it is in a very backward ſeaſon, and then it will not be prudent to feed wheat down at all;) I ſay, ſheep ſhould never be turned on it after the middle of February: the beſt time, in general, is the latter end of January, or even the middle of that month.

"If ſeaſonable rains follow, provided the ground is clear of weeds, it will be greatly to the advantage of the farmer.

"If the farmer has the leaſt doubt of the ſtrength of his land towards giving the checked plant nouriſhment, I would by all means have him afford his wheat a top-dreſſing of ſoot, aſhes, malt-duſt, or whatever other proper manure he may have at hand, provided he is ſure it is quite clear of weeds.

"Let not the induſtrious farmer be at all uneaſy if, after feeding down his wheat, he perceives the plants ſtand at a diſtance one from the other; for if he has practiſed this piece of huſbandry, with the precautions above noted, he may depend upon it, that every plant will throw out a number of branches, and that he will have a field full of ſtalks at harveſt, and a crop that will ſurpriſe him.

"I am very fond of recommending wheat crops to the farmer's attention, not only becauſe it is the moſt noble of grains, but alſo becauſe, if well managed, it is the moſt profitable.

"We muſt not always judge the farmer's profits by the produce of his land; which ſome of our readers may think odd; but I will make it appear by an example from my own practice.

"In the year 1743, I had two fields, of twenty acres each, in wheat; one of which yielded me, at harveſt, at the rate of four quarters an acre throughout; the other yielded me only twenty buſhels, one acre with another; yet I got more by the laſt than the firſt. The caſe was thus: falling ſhort of dung, I was obliged to buy; but it was ſo dear, that I only bought enough for the firſt field, giving the other two ploughings extraordinary, inſtead of manuring it; and theſe ploughings I reckon at a mere trifle, as my horſes would otherwiſe have ſtood ſtill." *Muſeum Ruſticum*, *vol.* III. *page* 151.

"I have often thought that it would be of great ſervice to the public, if, by any method, there could be determined a mean weight for any given quantity of corn, and likewiſe what number of grains, upon an average, ought to be contained in each ear, and the proportional weight between the ear, with the grains in it, and when taken out, and likewiſe the proportional difference between the weight of the whole ſtalk, including the ear and the grain.

"But in order to ſettle this medium, under our preſent conſideration, it will be abſolutely neceſſary, in the firſt place, to make accurate and impartial experiments for a number of years, and then, by comparing the produce and the weight, &c. of the whole, both ſeparately and together, we may come pretty near the mark in view.

"In order therefore to purſue the plan I had laid down, in the beginning of the harveſt of the year 1757, I got three

three ears of common red Lammas wheat out of —— field, Auguſt 26. I then cut off the ſtalk cloſe to the ear, which I weighed with the corn in it: I then weighed the grains when rubbed out of the ear, and cleared from the chaff: in the next place I compared the difference, and then counted the number of grains in each ear reſpectively; and at the end of every year ſet down the weight of a cubical inch of the product of that harveſt.

"But in order to give a clearer idea of my method of proceeding, I will ſet down the weight, &c. of the corn which was gathered from the firſt field, in columns, in the manner I entered it in a book kept for that purpoſe, which will be ſufficient to explain the whole without a multiplicity of figures.

Number of ears, when and where got.		Weight of the ear with the corn in it.	Weight of the grain when free from the chaff.	Difference.	No. of grains in each ear.
1757.		ʒ ə gr.	ʒ ə gr.	ʒ ə gr.	
Three ears got	1	0 1 5	0 0 19 5	0 0 5 5	28
in —— field,	2	0 1 2	0 0 17 5	0 0 4 5	27
Auguſt 26.	3	0 1 7	0 1 1	0 0 6	36
Total.		1 0 14	0 2 18	0 0 16	91

"I proceeded in the ſame method with each of the three ears taken out of fourteen other different fields, during the time of the ſame harveſt: then caſting up the ſum total of each column, and dividing their products by the number of ears gathered that ſeaſon, the quotient would give me the mean weight, &c. of an ear of that harveſt, and its number of grains, &c. &c.

"I then made a cubical veſſel containing exactly a ſquare inch; and having mixed all the corn together, I filled the above veſſel, and weighed its contents with the greateſt accuracy; which weight I ſet down, repeating the operation ſeven or eight times, having well mixed the little heap of corn together, after each trial, and then ſet down the weight of each as before: and as there would ſometimes be the difference of a grain or two more or leſs in each cubical inch, I divided the product of the whole by the number of times the experiment was made, and ſet down the quotient as the mean weight of a cubical inch of corn for that year, which in 1757 I found to be 3 dr. 12.3 gr. I have perſevered in this method every year ſince: but to avoid troubling you with the particulars of each, I will give you at one view the mean weight, &c. the number of grains in an ear, and the weight of a cubical inch for each of theſe laſt ſeven years paſt, and after that the medium of all taken together.

"I made uſe of apothecaries weights upon account of the ſmaller ſubdiviſions of the ounce into drachms, ſcruples, and grains, which I have afterwards, in reckoning up the weight of the buſhel, reduced to troy, and averdupois. But we will now give the reſult of the ſeven years experiments in the following columns.

A. D.	Mean weight of each ear with the corn in it.	Mean wt. of the grains alone.	Difference.	Mean No. of grains.	Mean weight of a cubical inch.
	ʒ ə gr.	ʒ ə gr.	ʒ ə gr.		ʒ ə gr.
1757	0 1 10 5	0 1 5	0 0 5 5	38	3 0 12 3
1758	0 1 5	0 1 0 5	0 0 4 5	30 4	3 0 13 3
1759	0 1 8 2	0 1 2 4	0 0 5 8	37 6	3 0 14 5
1760	0 1 14	0 1 4 4	0 0 9 6	36 8	3 1 4 3
1761	0 1 9 5	0 1 4 5	0 0 5	36 6	3 1 4 3
1762	0 1 17 4	0 1 8 3	0 0 9 1	36 5	3 0 16 5
1763	0 1 10 1	0 1 3 3	0 0 6 8	35 5	3 0 17
Total.	3 1 14 7	2 2 8 4	0 2 6 4	251 4	23 0 2 2
Mean wt.	0 1 10 67	0 1 4 05	0 0 6 62	35 9	3 0 17 457

The total divided by ſeven gives the mean weight, &c. &c. of the whole together, as in the preceding line.

"The firſt of the above columns (the date of the year not being reckoned) ſhews us, at one view, what we may expect a ſingle ear of Lammas wheat, ſeparated from the ſtalk, to weigh upon an average; and the ſecond what its produce in grain ſhould weigh when ſeparated from the chaff: the next diviſion gives the difference, being the weight of the ear and chaff alone without the grain; the fourth, the number of grains in each ear; and the laſt, the weight of a cubical inch; which latter we ſhall further conſider, and ſee what will be the mean weight of a buſhel, omitting the odd grains and decimal parts, as immaterial in ſo large a meaſure.

"As the ſtandard Wincheſter buſhel contains 2150.4 cubical inches, if the above weight of one, viz. 3 3 17.457 gr. be multiplied by that ſum, the product will be 73lb. 8 oz. 12 dwt. troy. But this ſtandard buſhel is in fact too ſmall, the real contents of a buſhel dry meaſure being 2178 cubical inches, which, according to that calculation, will give 74 lb. 7 oz. 19 dwt. which ſums reduced to averdupois weight will ſtand as follows.

Troy { 73 8 12 / 74 7 19 } equal to { 60 10 8 6 / 61 6 15 9 } averdupois.

"But it will be proper to take notice that none of this corn was weighed till thoroughly dry, and ſeldom till the harveſt after it was got, and ſometimes later; therefore there muſt be ſome allowance made for the loſs of weight by keeping: which I found upon trial to be about four grains yearly in a cubical inch, and conſiderably more the firſt year, eſpecially if the corn happened to be got in a wet harveſt: therefore I think we may fairly eſtimate the mean weight of a buſhel of wheat, containing 2178 inches, to be about 62lb. averdupois weight.

"I know that a buſhel of good wheat is, by the generality of writers upon agriculture, calculated at about 64lb.; but our preſent enquiry is not whether it is good or bad, light or heavy of its kind; but what is the medium betwixt the two extremes, in order the better to judge of its qualities, according as it falls ſhort of, or exceeds, that determined weight.

"The fields out of which corn was gathered for the above experiments, are moſtly ſituated within a circle of ten or twelve miles round the town of Warwick, and ſome of them in Northamptonſhire; and in ſoils of different

rent kinds, and ſuch as have been productive of good, bad, and indifferent crops.

"With regard to the obſervations, which I now offer to the public, they may be aſſured that they have been made with the greateſt accuracy, and, barring any errors in the calculations, without the leaſt deviation from the truth.

"My method of gathering the ears of corn was, to crop them ſtanding during the time of harveſt, always endeavouring, as near as I could gueſs, to take ſuch as were of a middling growth, avoiding the fulleſt ears, as well as thoſe which were ſhrivelled, or ſtinted. I therefore generally got them from about the middle ſpace between the ridge and the furrow; I then carefully wrapt up the produce of each field in ſeparate papers, to prevent the corn from ſhedding, or intermixing.

"The column which ſhews the difference between the weight of the ear with the corn in it, and that of the grains alone, is meant only as relative to the ear itſelf, without the ſtalk added to it, which latter was always ſeparated from it. But I have ſince made ſome few experiments with regard to the proportional weight between the whole ſtalk and ear, and its produce is grain; and I found the former to be to the latter as about ſixty-ſeven to ſeventy-two. But I cannot depend ſo much upon the juſtneſs of this calculation, as of the others, it being only tried upon the produce of one harveſt.

"It muſt be obſerved that the weight of corn will vary more or leſs by keeping, according to the nature of the grain itſelf, the ſeaſons that it has had for its growth and maturity, and the dryneſs or moiſture of it when reaped: for notwithſtanding, it was before obſerved, that there may be an annual loſs of about four grains in every cubical inch upon an average, yet it may ſo happen that the weight of it may even be encreaſed by keeping, as was really the caſe with regard to the corn which was got in the harveſt of the year 1762, after an exceſſive dry ſummer; for I found, upon weighing a cubical inch of the ſame corn, a year after the firſt trial, that it had actually encreaſed in weight 2.6 grains, which I can by no means account for, but upon a ſuppoſition that the corn contained in the ear, having been ſo thoroughly dried, whilſt ſtanding, by the preceding heats and great drought, there was no room for any further evaporation of aqueous particles; but that, on the contrary, being laid up in this extreme ſtate of dryneſs, it muſt even imbibe moiſture afterwards, from the coolneſs of the place where it was repoſited; by which means the grain would become more plump than when freſh gathered, and would conſequently encreaſe in weight. From hence the reaſon is very obvious, why corn that is thoroughly ripe, and well inned, will undergo a much leſs change by keeping, than that which has been plumpt up by preceding rains, though perhaps it may look better to the eye than the other. But I think it may be laid down as a rule, that the more the external coat of the grain is extended by redundant moiſture from within, the more will it appear ſhrivelled and wrinkled, whenever that moiſture is evaporated, which it muſt loſe upon being kept for any conſiderable time in a dry place: therefore it will be moſt to the advantage of the owner to have ſuch corn ſpent as ſoon as it is ſufficiently dry for common uſe, and not to hoard it too long in the granary, as the heap from the above-mentioned cauſe will be daily decreaſing.

"If further experiments of this kind were to be tried in other parts of this kingdom, and even in different climates; and if the reſult of each obſervation was to be compared with the others, we might probably come ſtill nearer to the medium which we have been aiming at; and the ſame trials might be made with any other ſort of grain." *Muſeum Ruſticum, vol.* II. *p.* 175.

"The experiments made by the above ingenious gentleman are very accurate, though, in my opinion, much too ſmall to determine matters of ſuch importance: but he has, I think, fallen into a miſtake that I alſo did in trying ſome experiments upon wheat, viz. in ſuppoſing that a middling ear is a ſtandard for computing the crop. This, indeed, would be the right rule, provided there was a regular gradation in the ears above and below the middle ſize: but, in fact, it is otherwiſe; there are generally more ſmall ears than large ones, and yet the corn in the large ears may weigh moſt.

"To explain this, let us ſuppoſe a perſon going to chooſe ſome middling ears as they ſtand in the field: he muſt do this either gueſſing by his eye, or by meaſuring ſome of the different ſizes, and taking thoſe of the middle ſize as near as he can. The ſizes can only be determined by their length and fullneſs: and if, for example, the longeſt are five inches, and the ſhorteſt one, the medium is three inches. Now, though thoſe of three inches are undoubtedly the middle ſize, yet, unleſs the weight and meaſure of the corn in the ears below three inches are equal to that of the ears above that ſize, the calculation of the crop from the three-inch ears will be wrong. This will be ſeen in the following tables.

"I once took an account of great part of a ſheaf of red Lammas-wheat; but having miſlaid my notes of it, I ſhall at preſent take notice chiefly of an experiment made upon white Lammas wheat, of the crop of 1762. The ears and ſtraw of this crop were in general very ſhort; but the corn was remarkably fine, full, and heavy. The wheat of this experiment was raiſed upon clover lay, and the crop about twenty buſhels upon an acre. A nine gallon buſhel of this wheat weighed above ſeventy pounds averdupoiſe, which is uſually reckoned the full weight of good wheat, though ſome will weigh more, as the beſt generally did that year.

"In February, 1763, I took ſome of this corn out of a middling ſheaf, and, as near as I could, of the middle-ſized corn: but it was taken out all together, and, without ſeparating of it. I ſorted what was thus taken out, into four parcels, nearly according to the length of the ſtraw, in order to diſcover the proportion between the ears and ſtraw of different lengths; but there ſeems to be little certainty in this.

"Theſe four parcels were weighed ſeparately ears and ſtraw together; then the ears by themſelves; and, laſt of all, the corn when ſeparated from the chaff.

"I weighed twenty of the firſt parcel by themſelves, that had the longeſt ſtraw, and longeſt fulleſt ears; and afterwards weighed them ſingly, taking the weight and meaſure of each, as in the table.

"Being deſirous to know the weight and produce of the ears of different lengths, I ſorted each parcel according to the length of the ears, differing one from another about half an inch; and I weighed theſe ſubdiviſions ſeparately, noting the length of the ears, and the number of cheſts and grains in each. The length of the ears was meaſured from the bottom of the loweſt cheſt that had any corn in it, to the top of the ear. The longeſt ear was three inches and a half, but there being only one of that length, it is included among thoſe of three inches and a quarter. The twenty ears firſt weighed are included in the ſixty-three large ears in this laſt weighing.

"Several

" Several ears have ſome very ſmall grains in them: theſe are ſet down in the table, but not reckoned in the weight, becauſe I ſuppoſed them not marketable, and that they would go to the tailing, or off-fall corn. Of theſe ſmall grains two thouſand one hundred and eighty-ſeven weighed an ounce averdupoiſe. The reſt were weighed by troy weight, as below.

The weight of the four parcels.

			oz.	dw.	gr.

20 ears		333	684 = 34.2 grains in each ear upon a medium.				

" In the firſt of the following tables are inſerted the aſſortments of the four parcels, by the length of the ears, with the number of cheſts and grains in each, and the ſeparate weight of the ears, grain, and chaff. I muſt obſerve, that by accident I miſſed taking the diſtinct weight of the two hundred and fifty ſmalleſt ears: they are ſet down in the table as I computed them, in proportion to the third, or preceding parcel, which may differ a little from the real weight; but this cannot be much, for the weight of the whole parcel is right.

" In the ſecond table, the length, weight, &c. of the twenty largeſt ears, are ſet down in the firſt line: in the ſecond line are the ſixty-three large ears, including theſe twenty: and the third line contains the two hundred and eighty-eight ſmalleſt ears. They are ſet thus together to give the more eaſy comparative view of them. The next three lines of this table ſhew the weight, &c. of all the middle-ſized ears, and of all thoſe above and below the middle-ſize, brought thus together alſo by way of compariſon. To theſe I have added, in the following columns, a calculation of the number of cheſts in each aſſortment of ears, and the mean number of grains in each cheſt; alſo, the number of grains, and weight of a mean ear, of each aſſortment.

" The laſt table ſhews the total weight of the corn, chaff, and ſtraw, upon an acre, agreeable to this experiment, reckoning the crop at twenty buſhels of nine gallons, or ſeventy pounds, averdupoiſe, per buſhel.

" The very ſmall grains are not reckoned here, for the above reaſons; and that the waſte in reaping, carrying, threſhing, and ſome left in the ſtraw, is more than they amount to. But by adding them, and allowing for about ſeven or eight inches long of ſtubble, the total weight of the crop may be nearly eſtimated.

A table of the length, weight, &c. of one thouſand two hundred and fifty ears, ſorted according to their length.

" Small experiments are not ſo ſatisfactory as large ones; and I could wiſh this had been more extenſive, but I had no thoughts of offering it to the public view till I read your correſpondent's letter, who has, I apprehend, gone upon a wrong rule in computing a crop, and has alſo choſen the mean ears too large: for, though the ears of red Lammas wheat are uſually longer than the white, it cannot be ſuppoſed that, upon an average, they are above double, both in weight and number of grains, as we find thoſe were to the mean ears of this experiment. Neither is it at all probable, that the mean ears of the common crops in any part of England, and in the ſame year, ſhould be heavier, and contain more grains in them, than the very largeſt ears of this experiment.

" The ears of this wheat being from three and a quarter to three quarters of an inch in length, the medium is two inches. I have ranged all theſe together in the ſecond table. They are a fair medium in regard to length; and they are ſo alſo as to fullneſs, becauſe they are all included: but, as appears in the table, they are not ſo in reſpect to the weight of the grain, which is the rule for the medium of the crop; for the ſmall ears are more than double the number of the large ones, and yet the large ears are the heavieſt. If, in order to make the number of ears equal, we chooſe the mean ears ſhorter than two inches, the inequality of weight will be greater than before; and if we take our medium higher than two inches, the weight may be made equal, but this will encreaſe the diſproportion in the number; and hence I think it is evident, that we cannot fix upon any ſize of ears that will give us a juſt medium of the crop. The ſame will happen in other crops, for they all vary one from another in the ſize and number of ears: and, as we cannot be certain of their real proportion as they ſtand in the field, it is impracticable to calculate a crop from thoſe of any ſize.

" The calculation of a crop from a mean ear is made by multiplying the weight of grain in that ear by the number of ears upon an acre. A mean ear of this experiment weighed, as in the table, 10.232 grains troy, and the crop was about twenty buſhels upon an acre. Your correſpondent reckons the weight of a mean ear at 24.05 grains troy, upon an average of ſeven years; ſo that, reckoning the ſame number of ears upon an acre as in this experiment, his crops will amount annually to forty-ſeven buſhels per acre, of ſeventy pounds, averdupoiſe, per buſhel. Theſe are ſuch crops as, I ſuppoſe, no conſiderable extent of contiguous lands in England produce annually; and are, doubtleſs, more than double the common crops upon an average.

" The diſproportion in the number of ſmall and large ears is very remarkable, and alſo their diſproportion in ſize: for, if we calculate from the twenty largeſt, we ſhall find that forty-three of them weighed as much as all the two hundred and eighty-eight ſmall ones, viz. one large ear produced as much corn as ſeven ſmall ones, and the grain in them alſo larger, and conſequently more flour in them: for one hundred of the large corns weighed ſeventy-eight grains troy, and one hundred of the ſmall but ſixty grains; ſo that four grains of the large ears were heavier than five of the ſmall. This great difference is not from any defect in the rudiments of theſe ſmall ears, but is occaſioned principally from bad culture, and a defective nouriſhment; becauſe we ſee that the plants raiſed from the ſame ſeed will have larger or ſmaller ears, according as they are cultivated. It might, however, be uſeful to know at what period of their growth thoſe ſmall ears are ſtinted, and whether they are produced from the original plant, or from the tillers. I am not furniſhed with experiments to determine theſe points, but recommend them to the enquiry of your readers.

" It is certain that the ears of wheat, in general, do not arrive to the ſize that they are naturally capable of: and if it was known at what period they are formed, the ſtinting of them might, in ſome degree, be prevented, by a dreſſing, or other culture, at that period. That there is ſome ſuch period in nature, may appear from other circumſtances in the growth of this plant. There is a particular ſeaſon for its tillering, or ſpreading; another for its upright growth; and one for its bloſſoming and forming the ſeed; and probably one alſo for the ear being formed: and the growth of it, in reſpect to each of theſe, may be promoted by culture, or retarded by a defect of nouriſhment, at theſe periods.

" When the ſeaſon of tillering is paſt, no culture will make this plant throw out more branches; and after the

ear is ſhot out, it is then impracticable to make it larger, viz. to encreaſe the number of cheſts. Again, when it has bloſſomed, no art will cauſe the ſtem to riſe higher. And, laſt of all, after the time of bloſſoming, there is no adding of one grain more than is already formed in the ear; though, in all theſe caſes, an addition, or improvement, may be made by culture, if applied at the proper time.

"It is therefore of importance to know the periods of growth of the different parts of the plant; and that if we happen to miſs aſſiſting of it in one, ws may improve it in another. If the ſeaſon is loſt to encreaſe the number of tillers, we may enlarge the ears; or, if that is alſo omitted, we may encreaſe the number of grains in the ears, and make them larger and fuller of flour.

"To ſhew this more plainly, with reſpect to the grain, let us a little conſider the ſtructure of an ear of wheat. The grain is placed in a cell, conſiſting of two valves, or leaves; and there is one leaf extraordinary on each outſide of the cheſts, which ſeems intended as a fence, or ſecurity, againſt accidents to the outward grains. The cheſts about the middle of the ear are the largeſt, and uſually conſiſt of four, five, and ſometimes ſix or ſeven cells: and the number of cells decreaſes towards the top and bottom of the ear. If the ear is examined when in bloſſom, we may ſee what number of grains each cheſt is formed to produce: or this may be ſeen afterwards by the number of double valves, which are properly the chaff, for theſe remain, though the grains have proved abortive; and therefore, by counting the leaves of chaff, allowing two to each grain, and two extraordinary to each cheſt, we ſhall find what number of grains each cheſt might have produced.

"The outward grains of the cheſts are commonly the largeſt, and ſmaller towards the middle, and often ſtinted grains, or none at all, in the middle cells; and this, notwithſtanding moſt of theſe had bloſſoms in them, and the grains had made ſome progreſs, or begun forming. They are later than the outſide grains, as if laſt impregnated.

"The number of theſe deficient, or miſſing grains, is greater than might be ſuppoſed without examining them. In a favourable ſeaſon moſt of the cells have grains in them; and, if examined at the time of bloſſoming, the grains may be ſeen in different degrees of maturity, many of them with the naked eye, and others with a good glaſs; but though they appear then in general to be freſh, and in a growing ſtate, a conſiderable number of them is afterwards ſtinted, or die away entirely. In an ear of red Lammas wheat, of ſix inches long, twenty-five cheſts, and two hundred and eighty-ſix leaves of chaff, I have counted ſeventy-four grains ſome time after bloſſoming; by which it appears, that this ear might have produced one hundred and eighteen grains; and yet at harveſt I have not commonly found above ſixty grains in an ear of that length. I have likewiſe this ſeaſon counted fifty-four grains in an ear of white Lammas wheat, of three inches and a quarter long, nineteen cheſts, and one hundred and ſeventy four leaves of chaff; ſo that this ear might have yielded ſixty-eight grains: but we ſee in the above tables, that the fulleſt ear, of the ſame ſort of wheat, and the ſame length, yielded only forty-one grains; and three of the ſame length, yielded but thirty-eight grains and one third each, upon an average.

"The tillage and dreſſing of land for wheat is done, for the moſt part, before the wheat is ſown, and the benefit of theſe gradually decreaſe; whereas the wheat requires a gradual encreaſe of nouriſhment, both in order to form large ears, and afterwards to fill them with large grain. And hence appears the great defect of the common huſbandry, and points out the advantages of top-dreſſing wheat in the ſpring with ſoot, or other light manure, which bring the plants a freſh ſupply of nouriſhment when they want it moſt; and hoeing, when they can be performed at the proper times, particularly the deep, or horſe-hoeing, has the ſame effect of producing large ears; and for filling them, the horſe-hoeing is the moſt effectual, as that can be performed at the critical time, and when the plants are large.

"It has been commonly ſuppoſed, by thoſe who practiſe the New Huſbandry, that the moſt important hoeing, for the purpoſe of filling the ears with good grain, is ſoon after the wheat has bloſſomed: but this, I believe, is a miſtake, and that it ſhould be performed immediately before the wheat blows; for before that is over, the grain is conſiderably advanced. I have found no leſs than ſeventy-ſeven grains in an ear of red Lammas wheat, of four inches and three quarters long, and at the ſame time a conſiderable part of the bloſſoms ſtill remaining on the outſide of the ear.

"This is above one third more than uſually comes to maturity in an ear of that length; ſo that it ſeems very probable the ears would produce near one third more corn than they commonly do, were they to be aſſiſted at that time with ſufficient nouriſhment. But this would come too late after the bloſſoming is over; for by that time, ſome of the weak grains die, and others are ſtinted, ſo as not to be recovered again by any future hoeings. A check at this critical time ſeems to have the ſame effect as it has upon a grain of corn, or other ſeed, after it has begun to vegetate: if that is put a ſtop to, it never recovers.

"From the great number of ſmall ears in a crop, and the deficient grains in all the ears, we may plainly ſee the advantage of good culture, and of taking the proper ſeaſons to apply it. The New Huſbandry is, in this reſpect, much to be preferred; and alſo becauſe much fewer plants will produce an equal crop; in which there are ſeveral advantages, beſides ſaving above half the ſeed. This method of culture is, indeed, ſo much ſuperior to the common huſbandry, not only in raiſing wheat, but plants of almoſt every kind, that it is to be wiſhed it was more promoted.

"I am ſenſible that ſeveral gentlemen have objections to this huſbandry, ariſing partly from a miſinformation of Mr. Tull's practice and ſucceſs, and partly from the difficulty they apprehend in overcoming the prejudices of the farmers to any new methods.

"That they are very tenacious of old cuſtoms, is readily admitted, nor are they to be too much blamed on that account: but that they cannot be prevailed with to alter them, upon rational evidence, and proper encouragement, is, it is apprehended, carrying the argument too far, as this tends to diſcourage all attempts of improvement.

One of the reaſons aſſigned, why the farmers cannot be brought to practice the New Huſbandry, is the difficulty of managing a drill-plough for ſowing corn, which is admitted, though that is not ſo great as ſome have ſuppoſed; for

for I have ſeen a huſbandman learn to manage ſuch an inſtrument, who, after one day's practice, could ſow with it four or five acres a day, with the proper quantity of ſeed, at a leſs expence than common ſowing and harrowing.

"Some have objected farther, that the farmers cannot practiſe this huſbandry, becauſe they are ignorant of its principles: but theſe principles are not many, nor hard to be underſtood, ſo far, at leaſt, as relates to practice; and, in fact, the practice of the New Huſbandry is eaſier than the old, becauſe it is founded upon clear principles, which often is not the caſe in the old huſbandry.

"It ſeems that ſeveral gentlemen are not for introducing this new method, becauſe they are not convinced that it is, upon the whole, better than the old. If we may credit thoſe who have gone furtheſt in the practice of the New Huſbandry, thoſe gentlemen abroad in particular, who have publiſhed their experiments, there ſeems to be no doubt of its ſuperiority: but as it is a matter of great importance, that this fact ſhould be fully eſtabliſhed to the ſatisfaction of all gentlemen, from whoſe influence and example the moſt valuable improvements are to be expected, the trial is not difficult, nor very expenſive: a ſmall farm, with ſome variety of ſoils in it, cultivated in the ſeveral methods, by way of compariſon, and exact accounts kept of the expence and produce of each, would determine this point without any reaſonable doubt.

"In matters of this ſort, ſpeculations and reaſonings are not to be relied on without experiments; and the larger they are, they will be the more convincing. Whether ſomething, like what is here propoſed, might not have the deſired effect, and likewiſe be a means of making uſeful diſcoveries in vegetation, and the culture of plants, is ſubmitted to the conſideration of thoſe who have at heart the improvement of agriculture.

"A more extenſive plan is neceſſary for introducing new methods into common practice, and which might comprehend the farmers, and alſo the huſbandmen, who execute and excel in the performance. It is recommended to your readers to conſider and propoſe what they think the moſt probable means for attaining theſe deſirable ends." *Muſeum Ruſticum*, *vol.* III. *p.* 38.

"It is certain, ſays another ingenious huſbandman, that many ſtrange reports were raiſed of Mr. Tull, and his huſbandry, by prejudiced perſons; and his book being printed for the author, ſome bookſellers were much offended, and employed ſeveral hands to write againſt him, which they did in a moſt ſcurrilous manner, aſſerting many things that were falſe, and miſrepreſenting others. Some of theſe he takes notice of himſelf, in the additional parts of his work. I ſhall mention only one inſtance how ready people were to give credit to ſuch falſe reports. "Laſt ſummer," ſays he, "the vulgar in general believed, in a country but twelve miles diſtant from me, that I always carried my dung and threw it into a river: now there is no river nearer to the barton where my dung is made, than is the fartheſt part of my land; ſo that the expence of loſing my dung would be greater than ſpreading it on any part of my farm. Beſides, I live in a country where farmers buy dung at a good price; but it is known that I neither ſell nor waſte any dung. Againſt ſuch lying tongues there is no defence."

"But a principal cauſe, that the reports of his bad ſucceſs in his wheat crops have gained ſo much credit, I believe, is, that the additions to his Eſſay are out of print, and not generally known; and it is chiefly with a view to inform your readers of them that I write this letter.

"Mr. Tull began his ſcheme of ſucceſſive wheat crops with four rows. Afterwards he found that three rows were better, and was in that practice, of drilling three rows upon a ridge, when he publiſhed his Eſſay. Upon further experience he found, that two rows produced as good crops as three or four, and were more eaſily managed. This he recommends as his laſt and beſt method; and altered his drill-plough to his practice of planting only two rows upon a ridge, of which he gives a cut and deſcription in his Addenda and Concluſion. By this alteration, his drill is much leſs complicated, and leſs difficult to manage, than that for planting three rows, deſcribed in his Eſſay.

"The gentlemen abroad, who are now promoting the New Huſbandry, have gone into the practice of planting three rows upon every ridge, ſuppoſing that to be the beſt method; and the drill-ploughs invented by M. Duhamel, and M. De Chateauvieux, are conſtructed to ſow three rows.

"From the practice of the gentlemen abroad, and other inſtances that might be given at home, it is evident, that they have not ſeen the additions that Mr. Tull made to his Eſſay, in which, beſides his different method of drilling, there are ſeveral very material improvements in the manner of hoeing and cultivating wheat, and other crops; and from theſe laſt parts of his work may be alſo ſeen, that the reports of his bad ſucceſs, in repeated wheat crops, are without any juſt foundation.

"In order to ſhew this more clearly, it may be proper to premiſe a ſhort chronology of the progreſs of his huſbandry, collected from his own account of it; in which it is to be obſerved, that as the year, at that time, was by ſome reckoned to commence the firſt of January, and by others the twenty-fifth of March, and the crops at other periods, it occaſions an uncertainty of ſometimes a year in this account.

Mr. Tull began his horſe-hoeing huſbandry about the year	1723
his ſucceſſive horſe-hoed wheat crops	1726
He publiſhed his Specimen	1731
his Eſſay	1733
his Supplement to the Eſſay	1735
his Addenda	1737 or 1738
His Concluſion is dated March 31,	1739

(All theſe are printed in ſmall folio)

He died about the year 1741.

"As to his practice of raiſing ſucceſſive crops of wheat, he made the experiment firſt upon part of a field, which had not been dunged for ſome time, and upon this part he continued to raiſe wheat for twelve years, without the aſſiſtance of any manure. In the preface to his Eſſay, he ſays, "The particular ſcheme of raiſing annual crops of wheat, without dung or fallow, is as yet only upon probation; but, by the ſix crops I have had in that manner, I ſee nothing againſt their being continued." In the Supplement, page 249, he tells us, "There is now the eleventh crop of wheat on the ſame field, (except that in the ninth year, by accident, of having contracted to let my farm, it was drilled with white oats) and I do not yet ſee any reaſon againſt its being continued for wheat annually,

as long as it is kept in this culture." In the Addenda, page 261, "The field which laſt year had the eleventh crop of wheat," (as in page 249) "has now the twelfth on it, very likely to be a good one." And in the concluſion, he ſays, that the twelfth crop of wheat, upon this field, "was the beſt, I believe, that ever grew on it." "It has now the thirteenth crop, likely to be very good, though the land was not ploughed croſsways;" which he mentions it was the year before, in order to alter the ſize of the ridges.

"I have here collected what he ſays of this field in particular, as it was his field of experiment, upon which he had raiſed the moſt crops of wheat, without any manure. Let us next ſee what crops he had upon his lands in general.

"He begins his Addenda with acquainting the reader, that he was required to take an exact account of the crop of an acre of horſe-hoed wheat, part of a field of twenty-five acres, in order to ſee the difference between that and the crop of a ſmall piece of ground, drilled upon the level, and hand-hoed. This acre being meaſured, and the crop reaped, and threſhed by itſelf, yielded twenty-nine buſhels and three pecks of clean wheat, nine gallon meaſure. But he obſerves that great waſte was made by the reapers of this acre, and ſome damage was done to the corn by cattle; for which allowance being made, he reckons the real produce of this acre to have been thirty-two buſhels, or four quarters of wheat.

"He then proceeds to give an account of the crops of wheat upon his other fields, which, including the above-mentioned field, were in all one hundred and ſix acres. The corn was not threſhed when he wrote this; but it appears, by his account of the crop, as I have computed it, that theſe one hundred and ſix acres produced, upon an average, nearly twenty buſhels of wheat per acre.

"If the quality of this land is conſidered, none of it rich, and the greater part light, and of a thin ſtaple, this cannot be called a bad crop. But there was another very important circumſtance, which ought to be conſidered: Mr. Tull was now advanced in years, and in a very bad ſtate of health; was frequently confined to his room, and ſometimes to his bed; inſomuch that, as he tells us, he had not ſeen ſome of his crops from the time they were ſown till the ſpring following. And in his Supplement he ſays, page 225, "My agriculture having been carried on by common day-labourers, without any body to inſpect them, (except when my diſeaſes ſuffered me to attend them, which, for ſeveral years laſt paſt, has been very ſeldom) cannot be expected to be all well managed; for though they can do it well when they pleaſe, yet their will being above controul, I muſt be content with their doing ſome tolerably well every year."

The duſt of the maſter's feet is a kind of manure ſo neceſſary in every ſcheme of huſbandry, that no perſon of experience in ſuch matters, who reflects upon theſe circumſtances, would have reaſon to be much ſurpriſed, if Mr. Tull's crops had really failed as much as has been ſuppoſed; and if we alſo take into the account, that theſe day-labourers whom he employed, and who had the management of his agriculture at the critical ſeaſons, were then generally, as ſuch men ſtill are, prejudiced againſt the new huſbandry, I think his ſucceſs, notwithſtanding theſe diſadvantages, is a ſtrong argument in favour of this huſbandry.

"But let us proceed to what Mr. Tull ſays further of theſe ſucceſſive wheat crops. In the Addenda, page 263, he tells us, "I have now ſix ſcore acres of wheat, an hundred acres of which are on the ſtubble of the laſt years wheat crop."

And in the concluſion, p. 273, "The crop of the ſix ſcore acres of wheat, that was growing at the time of publiſhing my Addenda, was much greater than the crop the year before it, and would have produced more grain in proportion, if the heavens had been as propitious; but the heavy rains that fell when the firſt planted was moſt in bloſſom, diminiſhed the filling of the ear and its grain, yet not ſo much as of moſt ſown wheat, eſpecially of the early-ſown, which generally eſcapes the beſt in this common calamity. The burn-baked wheat, being always early ſown, I am informed had next to no grain in it; and this is the moſt expenſive ſort of huſbandry, the tenants pay ſuch exorbitant fines for the liberty of ploughing this land."

Again, page 274, "The ſame ſix ſcore acres that was wheat the laſt year, is planted with wheat now, and is all of it as ſtrong and likely for a good crop as in any of the former years, though there is but about one acre of it dunged. The whole is the freeſt from weeds before hoeing that ever was ſeen, and the ſown wheat in the neighbourhood the fulleſt of them."

"I can ſhew, at this inſtant, one of the experiments I have recommended, which, though it be on leſs than two perch of ground, muſt convince every man who ſees it (and doth not renounce the evidence of his reaſon and ſenſes) that pulverization by inſtruments can vaſtly exceed the benefit of common manure.

"It is to ſuch experiments that I leave the progreſs of my horſe-hoeing huſbandry, aſſuring the public, that in all my practice, which is now thirteen years, I never have met with one inſtance that gives me the leaſt ſuſpicion of the truth of the principles I have advanced; and that, I believe, they have nothing to fear from enemies, but the falſe relation of facts, or fallacious arguments."

"Mr. Tull mentions here, that he intended this to be his laſt crop. He lived about two years afterwards. Whether he continued to occupy his farm, I am not certain; but if he did, and his crops were worſe than the preceding years, that could not be juſtly attributed to any error in the principles, but to the other cauſes above-mentioned. We ſee here that he appeals to an experience of thirteen years: nor can it be ſuppoſed, or admitted, that a perſon of Mr. Tull's underſtanding would go on from year to year to enlarge his plantations of wheat to the extent of one hundred and twenty acres, had he not been fully ſenſible of the advantage of ſo doing.

"The repetition of wheat crops upon the ſame land may, by many perſons, be ſuppoſed rather a matter of curioſity than of any great uſe; a change of crops being the general cuſtom, and ſuppoſed to be the moſt profitable: but this is not ſo clear as ſome imagine. The cuſtom is founded upon the ſuppoſition that change of crops is neceſſary; which, though it may be true in the old huſbandry, is not ſo in the new; and, without doubt, the change is often hurtful to the farmer; for, not to inſiſt on the extraordinary labour neceſſary to prepare the land, and the loſs of the ſeaſon, if it cannot be got into proper order in time, or, which is as bad, ſowing it, though not in proper tilth to receive the ſeed, the main point of all is, whether the

the profit of theſe ſeveral different crops is really more than hoed ſucceſſive crops of wheat, or other corn commonly propagated? In anſwer to this, I believe it is not very difficult to ſhew, by a fair compariſon of both, that the hoed crops are the moſt profitable, even including the clover and turnips in the old huſbandry. Nor is a profitable change of the crop, or the advantage of obtaining ſometimes three crops in two years, peculiar to the old huſbandry; for the ſame may be had to greater advantage in the way of hoeing.

"There is another circumſtance in the old huſbandry very unfavourable to the farmer. As he is under a neceſſity of changing his crops, he cannot adapt them to the ſoil. Moſt farms have land in them of very different qualities, and theſe are not equally proper for the production of plants of every kind. The ſtrong land, that is very fit for beans, wheat, and clover, is not equally ſo for peas, barley, and turnips. But the farmers commonly vary their crops according to the cuſtom of the country, and the conſequence is, that moſt of their lands are planted in their turn with crops not the moſt ſuitable to them; which is an inconveniency that may be avoided in the New Huſbandry.

"Having pointed out the additional parts of Mr. Tull's work, it is hoped that we ſhall ſoon have a new impreſſion; but as it may poſſibly be ſome time before the laſt parts of his work are re-publiſhed, I ſhall, for the benefit of ſuch of your readers as incline to practice the New Huſbandry, take notice of one or two important alterations in the horſe-hoeing culture.

"In the Eſſay, Mr. Tull directs, that the hoe-plough ſhould be brought as near as poſſible to the rows at firſt, and when the plants are young; but that the ſubſequent hoeings ſhould be at ſome diſtance from the rows, leſt the plough ſhould tear off too many of the roots, and deſtroy the plants; alſo that the laſt hoeing ſhould throw the earth of the intervals up to the plants, which he thought neceſſary for their better nouriſhment, when they were grown large. His laſt practice was different in both theſe reſpects.

"For in the Concluſion, page 272, he ſays, "At the ſecond hoeing, the plough goes in the furrow of the firſt, making it deeper and nearer to the wheat: the third hoeing fills up this furrow; and then, at the fourth hoeing, the plough goes in the ſame place as the ſecond, turning the mould into the intervals. It is remarkable, that though the furrows of the ſecond and fourth hoeings be deep and near to the rows, ſeeming to deprive the wheat of the mould which ſhould nouriſh it, whereby one would imagine, that theſe furrows, lying long open, ſhould weaken or ſtarve it; but it is juſt the contrary, for it grows the more vigorous: and it is the obſervation of my ploughmen, that they cannot, at theſe hoeings, go too near to the rows, unleſs the plough ſhould tear out the plants.

"If I may preſume to aſſign the cauſe of this ſurpriſing effect, it is in my opinion the following, viz. this open furrow has a double ſurface of earth, which, by the nitre of the contiguous atmoſphere, is pulverized to a great degree of minuteneſs near the row. The roots that the plough cuts off on the perpendicular ſide of the furrow, ſend out new fibres to receive the pabulum from this new-made paſture; and alſo part of this ſuperfine powder is continually falling down into the bottom of the furrow, and there gives a very quick growth to thoſe roots that are next it, and a quick paſſage through it into the earth of the interval, where they take likewiſe the benefit of the other ſide of this pulverized furrow. When it is ſaid that air kills roots, it muſt not be underſtood that it kills a plant, unleſs all, or almoſt all, its root is expoſed to it, as it is not in this caſe. Some think there are roots that run horizontally below the plough into the interval; but of this I am not convinced.

"It is not often that we plough above four times, and then the furrow is turned towards the row at the third time only.

"Whether theſe furrows lying long open next the rows, in very hot dry climates, may be prejudicial, cannot be known but by trials.

"The practical hoer will find this method of going cloſe to the rows of wheat, and other plants, of great ſervice to him; not only in the vigour of his plants, but alſo in the more perfect tillage of his land, and a conſiderable ſaving in hand-hoeing, weeding, and manure.

"The other circumſtance, of a large plant growing more vigorous, and the ſeed filling better, by ploughing the earth away from one ſide of it, is ſo ſingular, and oppoſite to the common practice of gardeners, that ſhould it ſucceed generally, it may lead to ſomething new in the theory of vegetation." *Muſeum Ruſticum, vol.* III. *p.* 159.

A comparative calculation of expence and profit between the drill and the common huſbandry, taken from Mr. Baker's report to the Dublin ſociety of his experiments in agriculture, for the year 1765. *Publiſhed by order of the ſociety.*

An eſtimate of the expence upon a plantation acre of wheat, in the common huſbandry.

	l.	*s.*	*d.*
To the firſt plowing, commonly called breaking, for fallow, eight horſes eight ſhillings; two plowmen one ſhilling and four-pence; two drivers one ſhilling	0	10	4
To the firſt harrowing, four horſes four ſhillings; a driver ſix-pence	0	4	6
To the ſecong plowing, commonly called gaurowing	0	10	4
To the ſecond harrowing	0	4	6
To the third plowing, commonly called ſtretching	0	10	4
To ſowing the ſeed, eight horſes eight ſhillings; two plowmen one ſhilling and four-pence; two drivers one ſhilling; the ſeed-man eight-pence	0	11	0
To ſeed wheat, one barrel	1	0	0
To rent for the year of fallow	0	18	0
To ditto, the year the crop is growing	0	18	0
	5	7	0

In this account forty ſhillings are charged for forty horſes, employed in the culture of one acre of wheat, in the common huſbandry; a charge which ought to be conſidered by the farmer, for he actually buys and maintains his horſes for this buſineſs.

The crop which follows wheat is generally oats; but ſometimes peas are ſown inſtead of oats; with ſome, the practice

practice is to let the peas follow oats, in which caſe they fallow only every fourth year; but where land receives no other aſſiſtance than what ariſes from fallow, it is a bad practice not to fallow every third year. It is the general practice to plow but once for oats, and therefore it ſhall be ſtated ſo; but it is a much better practice to plow the wheat ſtubble once before winter, and again in the ſpring.

An eſtimate of expence upon an acre of oats.

	l.	s.	d.
To plowing once	0	10	4
To ſeed oats, 2 barrels	0	12	0
To harrowing 4s. 6d. ſeed-man 4d.	0	4	10
To one year's rent	0	18	0
	2	5	2

Theſe two crops conſume three years; after which the farmer is to begin again, and to incur every article of expence ſtated in the above accounts, in order to obtain two crops more.

An eſtimate of expence upon a plantation acre of wheat in the drill huſbandry, the firſt year.

	l.	s.	d.
To plowing 4 times, to prepare the fallow	2	1	4
[This is the ſame charge as in preparing for the common huſbandry.]			
To harrowing twice for ditto	0	9	0
[This is the ſame alſo.]			
To rent for the year of fallow	0	18	0
[This charge is ſaved after the firſt year.]			
To harrowing with the drill harrows	0	0	6½
[Four acres a day may be harrowed with one horſe.]			
To ſowing with the drill plow	0	1	1
[From 3 to 5 acres may be ſown in a day.]			
To ſeed-wheat, generally 5 ſtone, but ſuppoſe 6	0	6	0
To the firſt, or winter hoeing	0	1	7
[Two acres may be hoed in a day, two horſes, plowman and driver: the deſign of this hoeing is to leave the plants dry, and to meliorate the earth.]			
To the ſpring hoeing with the cultivator	0	1	1
[To deepen the ſoil, one horſe, plowman and driver.]			
To the 3d hoeing, *i.e.* to return the meliorated earth to the corn	0	1	7
[To make the corn tiller, *i.e.* to encreaſe its branches.]			
To the fourth and final hoeing	0	1	1
[To fill the grain and render it large.]			
To rent, the year the corn is growing	0	18	0
	4	19	3½

N. B. Although the drill culture for the firſt year is very near as expenſive as the common, yet, after taking the firſt crop, the expence and labour of fallow, and loſs of time, is not to be incurred again, as is unavoidable in the common huſbandry.

An eſtimate of expence upon an acre of drilled wheat, after the firſt crop.

	l.	s.	d.
To plowing the land once	0	10	4
[One plowing is all that is neceſſary.]			
To harrowing with the drill harrow	0	0	6½
To ſowing with the drill plow	0	1	1
To ſeed-wheat	0	6	0
[Be it remembered, 5 ſtone is enough.]			
	0	17	11½
To four times horſe-hoeing, as before ſtated	0	5	4
To one year's rent	0	18	0
	2	1	3½

Thus the land is ſown again with wheat every year, and inſtead of 4*l.* 9*s.* which is the farmer's expence in the common huſbandry, excluſive of one year's rent of the land: in the drill method it is no more than 17*s.* 11½*d.* and the total expence, inſtead of 5*l.* 7*s.* is no more than 2*l.* 1*s.* 3½*d.* rent included; whereby there is a ſaving of 3*l.* 5*s.* 8½*d.* an acre.

Before the account of profit and loſs upon theſe different methods of culture be ſtated, it will be neceſſary to take notice of an objection, which may perhaps be made to the above charge of plowing in the common huſbandry. It is pretended, that three quarters of an acre may be plowed in a day, with one plow: but can it be done effectually? The land may, indeed, be ſcatched, but cannot really be plowed as it ought to be. The farmer ought to be cautioned againſt a trick too frequently practiſed in plowing. When a plowman enters his plow, and paſſes acroſs the field, he turns a ſod about a foot broad; when he is to return, he enters his plow about four feet diſtant from the outſide of the former furrow, and ſo turns another ſod of the ſame breadth, which, when turned, juſt meets the former ſod; thus four feet of the land appear to be plowed, whereas the fact is, that the two feet lying under the ſods is not touched with the plow at all. This deception, added to the practice of juſt ſkimming the ground, enables hirelings to undertake plowing at 6 and 7*s.* an acre. But if a plantation acre of land be well and effectually ploughed, 10*s.* 4*d.* as charged above, will not appear too much; and it is, in fact, ſupported by the common courſe of buſineſs. When wheat is to be ſown, it is the general cuſtom to ſend a barrel of ſeed into the field with two plows, which is to ſow an acre of land, and that is the uſual day's work for two plows in the general courſe of buſineſs. Let us ſee then, what the expence will amount to. Eight cattle will be 8*s.* two plowmen 1*s.* 4*d.* two drivers 1*s.* and the ſeedſman 8*d.* which in all makes 11*s.* and correſponds with the above charge.

To clear profit ariſing upon an acre of land in fifteen years in the common huſbandry -	27	19	2
Greater profit on the drilled acre, in fifteen years ——— ———	24	4	9

Which amounts to 1 *l.* 12 *s.* 3¾ *d. per annum*, for fifteen years on the acre, more than by the common huſbandry.

In the drill huſbandry the crops are ſtated at three barrels of wheat leſs upon an acre than in the common huſbandry, that it may not be ſuppoſed to be over-rated; but in the common huſbandry, the crops are rated at the higheſt; fourteen barrels of oats an acre, are alſo allowed in the common huſbandry, which every farmer muſt admit to be a great allowance upon the general produce.

That the drill culture will produce ſix barrels an acre, is fully proved in Mr. Baker's report at large, which will be ſhortly publiſhed, where it will be ſhewn, that much more has been produced.

Doubtleſs, it will be obſerved, that in fifteen years fourteen wheat crops are obtained in the drill huſbandry; in the common huſbandry only five wheat and five oat crops; the five other years are not only loſt, but are an heavy expence to the farmer.

A farmer having forty acres of tillage, ſuppoſing him to direct his attention to bringing it to the drill culture, would make in fifteen years 969 *l.* 10 *s.* more than he can in the common huſbandry; which is ſuch an advantage, that the greater profit in the drilled acre in fifteen years will purchaſe the fee-ſimple of that in the common huſbandry, at twenty-ſeven years purchaſe, valuing the land at 18 *s.* an acre.

Thus it appears, that in every fifteen years the fee-ſimple of all the tillage lands of the kingdom, is loſt to the community by the common courſe of tillage.

In

In ſtating theſe accounts, no mention is made of fences, water, cutting the land, weeding and reaping, as theſe articles of expence depend on a variety of circumſtances, but, in general, will be more on the common huſbandry than on the drill.

Though we, happily, in this kingdom, are not under the ſame neceſſity as ſome foreign countries, of building large edifices for public granaries, becauſe our harveſts are much leſs apt to fail us; yet as this work is perhaps too preſumptuouſly, intended for general uſe, it is incumbent on me to ſpeak of thoſe effectual, though expenſive means of guarding againſt dearth, or even famine, as well as of the cheaper and eaſier methods, by which every farmer may be enabled to enjoy the advantage of preſerving a large quantity of corn in a ſmall ſpace, without danger of its heating and fermenting, of its being preyed upon by deſtructive animals and inſects, or of its being ſpoiled through the ignorance, or want of judgment, of inattentive ſervants.

Corn reaped in a dry year, and eſpecially that of the growth of a hot country, is well known to be the moſt perfect, and the fitteſt for keeping: as, on the contrary, experience has proved that the ſofter and leſs ripened grains of wet years and rainy harveſts ſhould always be diſpoſed of for more immediate uſe, though their too great humidity, which would infallibly occaſion a putrefaction, if not remedied in time, may be exhaled, and they may then be preſerved a long while in very good condition, as will be ſhewn from repeated facts and proper experiments.

The ancient Romans imported annually vaſt quantities of corn from Egypt, a very hot and dry country, ſcarcely ever watered but by the periodical overflowings of the fruitful Nile; and they found this grain anſwer much better than any of their own growth, both for yielding plentiful crops, when ſown in Italy, and for keeping in their public granaries, where they frequently preſerved it many years, perfectly ſound. Pliny tells us, that, in his time, they kept corn a long while in ſubterranean caverns, made in a dry ſoil, and ſo cloſely ſtopped that not a breath of air could enter. They then covered the bottom with ſtraw, and laid upon that the corn in the ear. We have the concurrent teſtimony both of the ancients and moderns, that it will keep thus perfectly well for at leaſt ſix or ſeven years; and an accident, not long ago, diſcovered a parcel of corn thus preſerved at Amiens, where, though it had been laid up during a great number of years, it was found to be freſh and good, neither worm-eaten, rotten, nor mouldy. This was certainly owing to the moiſt air having been kept out, and with it the eggs of animals, and ſeeds of thoſe minute vegetables which we ſee in form of mouldineſs on ſuch corn as has been leſs carefully defended from their acceſs. In effect, experimental philoſophy has proved that the air is the great ſource of corruption; for even the moſt corruptible ſubſtance, ſuch as meal, butter, milk, and the like, have been preſerved freſh four months in the exhauſted receiver of an air pump.

There ſtill is, near grand Cairo, a vaſt ſubterranean magazine of corn, defended with good walls, and called Joſeph's granaries. It is hardly to be ſuppoſed that they are quite ſo old as the days of that patriarch: but they abundantly prove the utility of ſuch places of ſtore, by the vaſt quantities of grain annually preſerved in them.

Many parts of Africa, the corn of which country, and particularly that about Algiers and Tunis, will keep much longer than the growth of any other place, abound with granaries of this kind. They are deep pits made in the ſolid rock, but juſt wide enough at their top for a man to go down into them, but they grow larger immediately after, and are uſually ſquares of from thirty to forty feet in diameter. In theſe, the great men of the country preſerve their corn. They firſt cover the floor with ſtraw, then ſpread upon that a layer of corn, upon this another, but thin, bed of ſtraw, then another couch of corn, and ſo on, till the whole cavity is filled; obſerving all the while, as the heap riſes, to place ſtraw between the corn, and the ſides of the walls. When this is finiſhed, they cover the mouth of the entrance with a ſort of hurdle, over which they lay about two feet thick of ſand, and over this they raiſe a ridge of earth, well beaten together, in order to throw off the rain both ways, that none may ſettle on the place and ſoak into the magazine. The corn thus ſtored up always keeps three, four, or more years very ſound; and not unfrequently the proprietor being taken off by the cruel deſpotiſm of the Eaſtern governments, the magazine is forgotten, ſome accident diſcovers it many years afterwards, and the corn is almoſt always found perfectly good in it. All the care they take, by way of preparing the grain, is to expoſe it two or three days to the heat of the ſun, to dry it thoroughly before they carry it into the magazine.

In the dutchy of Lithuania, and in the Ukraine, the people always preſerve their corn in nearly the ſame manner, in wells or pits made in dry places: but great care muſt be taken there in the opening of theſe ſtores; for people who have deſcended into them, before they had had ſufficient communication with the freſh air, have been killed by the damps.

The Ruſſians too preſerve their corn under ground, in deep pits of almoſt the figure of a ſugar loaf, wide below, and narrow at top. The ſides are well plaſtered, and the top is covered with ſtones. They are very careful to dry their corn well, generally by means of ovens, kilns, or ſtoves, for their ſummer is too ſhort to effect it ſufficiently, before it is laid into theſe repoſitories.

The ſame thing is practiſed with unvaried ſucceſs in the iſland of Malta: and alſo in Gaſcony, the Vivarais, and other ſouthern parts of France, the corn of which is remarkable for keeping many years longer than that of any other province in the ſame kingdom. M. Duhamel tried this method in the Gatinois: but his corn was ſoon ſpoiled there by its humidity when laid up; that country being ſubject to wet and moiſture, and his grain, in this trial, not having been previouſly dried in an oven or ſtove.

Upon the whole, it is evident from theſe, and from many more inſtances, which might be alledged, of the practice of other countries, that ſubterraneous granaries properly made in a thoroughly dry ſoil, are the beſt of all repoſitories for the keeping of corn: but, at the ſame time, experience ſhews that this method will not ſucceed in our climate, the ſun here not having power to exhale the moiſture from the corn, ſufficiently to prevent its fermenting when laid in a large heap. I muſt likewiſe add, that when one of theſe ſubterranean magazines is opened and expoſed to the air, it muſt be emptied immediately, and the corn taken out of it muſt be thoroughly ſifted and ſcreened, or it will ſoon corrupt. Some think it more nouriſhing, when it has been well preſerved, than that which has been kept in granaries above ground.

The marquis of Santa Cruz, author of many excellent remarks on the political and military ſtate of different nations,

tions, obſervcs, that the corn of Galicia and the Aſturias will hardly keep from one year to another, becauſe of the humidity it contains, which rots and decays it: but that the corn brought thither from Caſtile will keep good many years. This laſt is therefore the only kind that the Spaniards ever venture to lay up in their public granaries: and the ſole difference, in M. Des Landes's opinion, between it and their other ſorts, is, that it grows in a country where there is leſs rain in ſummer. They might indeed, if their religion and policy did not forbid their having intercourſe with the Moors of Barbary, once their conquerors, eaſily import from Africa plenty of ſome of the beſt corn that the world affords, perfectly ripened, thoroughly dried, and, in all reſpects, fit for keeping many years.

The great objection to public granaries, even in countries where the uncertainty of the climate, the indolence of the people, the ill-judged form of government, and various other cauſes frequently combine to render them highly neceſſary, is the expence attending ſuch eſtabliſhments; generally ſo great, that none but a monarch, or a ſtate, can properly undertake them: and they, moſt certainly, cannot do any thing more laudable, more truly noble, in countries whoſe misfortune it is to be expoſed to the dreadful calamities of want and famine, or to depend upon the precarious aſſiſtance of their neighbours.

Tho' ſubterranean repoſitories for the keeping of corn are preferable to all others in countries proper for them; yet, even the common granaries may, with due care, and perhaps ſome few alterations, be rendered much more ſerviceable than they generally are. The principal cautions neceſſary to this purpoſe are, 1. To guard againſt the too great humidity which always prevails in places where there are many doors and windows: 2. To prevent a too free acceſs of the external air, becauſe this brings in with it the eggs of a vaſt number of different inſects, which prey upon and deſtroy the corn: and 3. To take care that the corn be thoroughly dry, and as clean as poſſible, when it is laid up. Theſe are the three general rules to prevent its corrupting.

The chief cautions to be obſerved in the erecting of granaries are, to make them ſufficiently ſtrong, and to expoſe them to the moſt drying winds. Sir Henry Wotton, and Mr. Worlidge agree particularly in theſe; both judiciouſly adviſing a northern aſpect for theſe buildings, becauſe that quarter is cooleſt and moſt temperate; and the latter rightly obſerving, in general, that the beſt granaries are thoſe built of brick, with quarters of timber wrought in the inſide, whereto to nail well joined boards ſo cloſely to the wall, that there be no room for vermin to ſhelter themſelves. Floors of plaſter are reckoned the beſt, becauſe they are cool in ſummer, and if well made, do not retain dampneſs in the winter. There may be ſeveral ſtories one above the other; for the ſhallower the corn lieth, the better it will keep, and the more eaſily it is turned. Some have a ſmall hole in the floor of their upper granary, thro' which the corn deſcends into the lower one, like the ſand of an hour-glaſs; and after it is all come down into the loweſt granary, it is conveyed back into the upper one; ſo that it is kept in continual motion, which is a great means of preſerving corn.

The granary in the city of Schönbank, in the vale of Parinburg upon the river Elbe, which is a ſtore-houſe for the wheat of which the mum is made at Brunſwick, is built nearly in this manner. It is three hundred feet long, eighteen feet wide within, has ſeven ſtories, each of which is ſeven feet high, and large windows all around, to open and ſhut cloſe according as the wind ſits. By this means, the droſs and duſt are carried off as the corn is turned; for which a weſt wind is always preferred, becauſe it is the drieſt. At each end of this granary, and in the middle, are ſtoves for fire in damp weather, and at the going away of great froſts and ſnows, to prevent moiſture. There are alſo on each ſide of this building three long troughs or ſpouts, in the upper loft; and in fair weather men throw the corn out of this loft into thoſe ſpouts, through which it falls into others, about ten feet wide at the top, and eight or ten inches at the bottom, by which it is conveyed into the lower ſtory, from whence it is wound up again by a crane fixed in the upper loft. By thus falling from one ſtory to another, the corn is cleanſed by the wind from all duſt and chaff, and receives the benefit of the air, &c. Theſe troughs, or ſpouts, are put on and taken off as occaſion requires, to any of the windows; that when veſſels come to lade corn, it may be conveyed, through them, into the proper barges, without being carried thither by men, or cattle. The wall of the two firſt ſtories is two bricks and a half thick, that of the three next is two bricks thick, and the thickneſs of the two uppermoſt is a brick and a half. Fourteen thouſand quarters of corn may be kept in this granary.

Mr. Mortimer, who gives us this account, which is taken originally from captain Andrew Yarranton's England's Improvement by Sea and Land, adds, that the ears of corn, cut off from their ſtalks, and packed up cloſe in a tight caſk, will keep very well, and that this is the beſt, he indeed ſays, the only way of carrying any ſort of corn over the ſea, in order to ſow it in a foreign country.

The public granaries at Dantzick are ſeven, eight, or nine ſtories high, and have a funnel in the middle of every floor, to let down the corn from one to another. They are built ſo ſecurely, that the corn does not contract any damp, though they are ſurrounded with water on every ſide, in ſuch manner that veſſels come up to the very walls for their lading, which is let down into them, likewiſe thro' pipes or funnels, with very little labour and charge. No houſes are ſuffered to be built near them, for fear of accidents by fire.

At Zurich, in Swiſſerland, corn is kept eighty years, or more, in the public granaries, which are very ſpacious, and well aired by means of many ſquare wooden pipes which paſs through them.

The twelve companies of London, with ſome other companies and private perſons, had formerly their granaries at the bridge-houſe in Southwark, under the ſuperintendance of a juſtice of the peace, a ſteward, and two maſters. Theſe granaries were built on two ſides of an oblong ſquare (now uſed for a wharf,) one of which ſtood north and ſouth, and was near an hundred yards long. Along this ſide were lattice windows which faced the north-eaſt; and on the other ſide, which was about fifty yards long, the windows looked to the north. The oppoſite ſides had no apertures. All the windows were about a yard high, without any ſhutters, and ran on in a continued ſeries, with very ſmall partitions, ſufficient only to nail the lattices to. Each of theſe granaries was three or four ſtories high; but the loweſt, or ground ſtory, which was twelve feet high, was uſed only for a ware-houſe.

In Kent, two ſquare holes are made at the end of the floor, and a round one in the middle, by means of which the corn is thrown from the upper into the lower rooms, and back again, the better to turn and air it. The ſcreens uſed on this occaſion are made with two partitions to ſeparate the duſt from the corn. The duſt falls into a bag, and when it is ſufficiently full, it is thrown away; the pure and good corn remaining behind. By theſe means corn has been kept thirty years in this country: and it is obſerved, that the longer it is kept, the more flour it yields in proportion, and the purer and whiter the bread is; only the ſuperfluous humidity evaporating in the keeping: for grain does not diminiſh in weight or bulk, after the firſt year.

The uſual way of preſerving it in our common granaries is, after it has been well ſifted and ſcreened, to ſpread it upon the floor about ſix inches thick, to turn it twice in a week, and to repeat the ſcreening of it once a week, during the firſt two months. It is then laid a foot thick, for two months more; and in this time it is turned once a week, or twice, if the ſeaſon be damp, and now and then it is ſcreened again. At the end of five or ſix months, it is raiſed to the thickneſs of two feet, turned once a fortnight, and ſcreened once a month, or as occaſion requires. After a year, it is laid two feet and a half or three feet deep, turned once in three weeks or a month, and ſcreened in proportion. When it has lain two years, or more, it is turned once in two months, and ſcreened once in three, and how long ſoever it is kept, the oftener it is turned and ſcreened, the better the grain will be preſerved. An empty ſpace, about two feet or a yard wide, is always left on each ſide of the corn, to prevent its running down holes or chinks at the edges of the floor, and to remove it from all moiſture that may proceed from the ſweating of the walls, or from any defect in the roof; and another ſpace is commonly left along the middle of the heap, if it be a wide one, to facilitate the turning of it as often as is needful. This is the general cuſtom; and experience has ſhewn it to be neceſſary in the uſual manner of keeping grain.

But all the foregoing methods of preſerving corn in granaries above ground are attended with very great expence, by reaſon of the vaſt buildings, which they require, and the many ſervants neceſſary to be employed to take care of theſe ſtores: beſides which, too much depends here upon the aſſiduity, ſkill, and probity of thoſe ſervants; and the grain is ſtill liable to be preyed upon, waſted, and ſpoiled, by vermin and inſects.

To obviate theſe inconveniencies, and to point out an eaſier, cheaper, and ſurer way of keeping all ſorts of grain, is the principal deſign of M. Duhamel's excellent Treatiſe on the Preſervation of Corn; in which, after rightly noticing the ſeveral diſadvantages attending to the common practice, he propoſes a method founded in reaſon, and on his own repeated experience, as well as that of others, whereby a large quantity of corn may be preſerved in a ſmall ſpace, during a number of years, without danger of its heating, fermenting, or contracting a bad ſmell or taſte, and ſecure from the ſpoil of animals and inſects, at a trifling expence, and with very little trouble. All theſe deſirable ends may be obtained, in ſome caſes, by ventilation only; in others, by drying the corn in a kiln over a ſtove; and in others again by both theſe methods. *See the article* VENTILATION.

A letter to Dr. Templeman, ſecretary to the ſociety for the encouragement of arts, manufactures, and commerce, deſcribing a new invented granary for preſerving grain.

"SIR,

"Where public utility is in queſtion, a private apology becomes unneceſſary: accept, therefore, without ceremony, the following hints to be laid before the ſociety.

"I have long been of opinion, that a method of preſerving grain from decay is much wanting; but it muſt be, to anſwer any good purpoſe, eaſy in its execution, and cheap in its proceſs.

"The method now practiſed, of laying wheat in a room or granary, and turning it frequently with ſhovels, and ſometimes ſcreening it, is ſubject to many inconveniencies: it muſt be laid very thin, or it is apt to ferment; and by being laid thin it takes up ſo much ſpace, that to lay up and keep five hundred quarters for three years only, would be conſiderably expenſive.

"Could we preſerve our corn for a number of years, it would not only be of great ſervice to the public, but of no ſmall benefit to the farmers. For want of doing this, we find a great, and often a ſudden, variation in the price of bread-corn: wheat will one year ſell for five pounds a load, (that is, five quarters) and the next year it will riſe to fourteen or fifteen pounds or even higher.

"The rents of lands are of late greatly riſen, owing to the encreaſe of our trade; ſo is the price of all kinds of labour, inſomuch that when wheat is low in price, the great farmers are conſiderable loſers, and the poor ones are ruined: this is one reaſon why our lands are ſo much monopoliſed as they are in ſome counties. The great farmers, being rich, can afford to be loſers for ſeveral ſucceſſive years, as they are ſure that once in a while the markets will riſe, and not only repay all their loſſes, but ſecure them a large profit. The poor farmers are under a neceſſity of ſelling their corn before the winter is paſſed: if the markets are low, they fail in the payment of their Michaelmas rent, their ſtock is in conſequence ſeized, and ſome over-grown monopoliſer in the neighbourhood adds their little plot to the many formerly ſeparate farms he already holds.

"Were the intereſt of the community to be conſulted, no man ſhould be allowed to rent above three hundred acres of land: the profits of ſuch a farm will, with proper regulations, maintain a family decently and well; and it is not requiſite, or even ſalutary, that farmers ſhould acquire large fortunes.

"But to return to my ſubject. Were a proper method projected for keeping wheat good for a number of years at a ſmall expence, all this would be remedied, our lands would no longer be monopolized, and corn would from year to year vary very little in price. This ſtands to reaſon; for in a very plentiful year a farmer would not ſell his corn too cheap, if he had the power in his hands to lay it up without great charges; and when the crops by any accident failed, the price of corn would not greatly riſe upon the poor manufacturer and labourer, as what had been ſome years before laid up would now of courſe be ſold at a reaſonable price, and make up the deficiency, and this without loſs to the farmer, and with great benefit to the community in general.

"This

" This intereſting ſubject has, for many years, employed my thoughts and attention; and I have in conſequence imagined, and even executed in miniature, or rather in ſmall dimenſions, a plan, which will, I have reaſon to think, anſwer the important purpoſes above-mentioned: my whole plan conſiſts in building a proper granary, (the conſtruction of which will not coſt much) which will keep corn for any number of years ſound, ſweet, and good, and that with very little annual expence.

" I imagine the following poſtulata will be allowed.

" If we can preſerve corn from fermentation, it will be in a way of keeping.

" To keep it from damp and moiſture, is the beſt means of preſerving it from fermenting.

" To move it frequently, give it air at proper times, and ſeparate the duſt and other extraneous matter, is certainly the beſt way to keep it from being moiſt and damp.

" Deſtructive inſects are to be kept from it, which by frequent ſtirring is beſt effected.

" I imagine there are few, who have made this part of nature their ſtudy, but will allow the above poſitions: I ſhall therefore, without farther prelude, inform you in what manner I effect this at a ſmall expence.

" The granary I would recommend conſiſts of ſeven ſtories of floors, and may be built in any dimenſions, provided proper proportions are adhered to.

" The form of it is ſquare; and I ſhall at preſent ſuppoſe it to be fourteen feet ſquare within the rooms or cells; the diſtance of the floor from one cell to the floor of that above it is to be five feet: and the whole building ſhould ſtand on ſtrong poſts, more or leſs in number according to its dimenſions, at the diſtance of ſix feet from the ground: the ſmall ſtairs, or rather ladder, to go to the ſeveral cells, muſt be fixed to the outſide of the building ſide-ways, with a leading rail or rope to prevent falling.

" The whole granary is to be built of what is generally called brick-noggin; that is, the whole is firſt framed in ſtrong timber-work, and the interſtices filled up with brick-work: the floors, beams, and joiſts, muſt be made ſtrong to bear the weight of the corn; the inſide of the cells muſt be well lined with dry oak-boards, cloſe jointed, ſo as to leave no cracks; and the outſide muſt be weather-boarded, the boards being ſtrongly nailed to the timber-work of the frame, and afterwards payed over with pitch. The floors of the cells muſt be ſo contrived as to ſhelve towards the middle, in which part is to be an aperture ſix inches ſquare, to be opened, or cloſed, by means of a ſliding ſhutter, which muſt have a long handle reaching in a grove without the granary.

On three ſides of the rooms there muſt be a window, ſtrongly latticed, covered with wire to keep out larger inſects and birds, and with ſtrong ſhutters to defend the corn from the weather: on the fourth ſide is a door to each room to open from without: the windows are to be ſmall, and as cloſe as poſſible to the cieling: over the upper room or cell for the corn is a loft, on the outſide of the door of which is fixed a crance to be worked within, by a winch and flyers.

" The uſe of the windows in the ſides of the rooms, is to give the corn all the benefit it can receive from the wind and freſh air: the door, when the cell is empty, gives the workmen entry to ſweep, duſt, and clean it.

" My method of managing my corn in this granary is as follows.

" When my wheat is thraſhed and cleaned, it is put up into ſacks and carried to the granary: the apertures I mentioned above to have been contrived in the floor of the cells are then opened, except two, viz. one in the floor of the undermoſt cell, and that in the floor of the ſecond cell, reckoning from the bottom.

" The ſacks are then craned up into the loft, and emptied, through a hole made for the purpoſe, into the uppermoſt cell, whence it falls through the apertures till it reaches the floor of the undermoſt cell but one, where it is ſtopped by that apperture being ſhut.

" When this cell is filled to the height of about two feet from the floor, which may be ſeen through the lattices, the aperture in the floor of the third cell is ſhut by means of the ſlider: the workmen then continue craining up the ſacks till all the cells are filled in the like proportion, except the undermoſt, obſerving the proper opportunities of ſhutting the apertures.

" In this condition the corn is left for a week, or ſomewhat longer, if it was got in very dry.

" The firſt ſtirring it receives, occaſions very little trouble: when it has been in the granary about a week, a workman, after having ſwept and cleaned the undermoſt cell, which was left empty, opens the aperture in the floor of the ſecond cell, by drawing the ſlider back: this lets the corn fall from the ſecond, into the undermoſt cell, the windows of which being open, the corn receives great benefit, as it falls, by the current of air that paſſes thro' the cell.

" When the ſecond cell is empty, the aperture in the floor of it is ſhut, and the workman, going in at the door, by means of the ſtairs on the outſide of the granary, ſweeps it and cleans it from all impurities, in order to prepare it for receiving the corn of the third cell, the aperture of which is next opened, and the floors being all made ſhelving towards the middle, the corn falls gradually through, in the ſame manner it did from the ſecond to the undermoſt cell.

" In this manner they are all managed, till at laſt the uppermoſt cell remains empty.

" It is then left for another week, when two workmen muſt for a ſmall ſpace of time be employed: one of them goes up into the loft at the top of the granary, to work the crane, and the other takes his ſtation on the ground under the floor of the undermoſt cell: under the aperture in this floor he firſt fixes a ſcreen, upon which the corn falls, and then, by means of a conductor at the foot of the ſcreen, drops into the mouth of a ſack which hangs to it, the bottom of the ſack reſting on a miller's hand-barrow: when all is prepared, he draws away the ſlider and lets the corn fall on the ſcreen.

" When the ſack is full, the ſlider is for a moment cloſed, till another ſack, on another barrow, is put under the conductor: the workman then wheels the firſt ſack to the outſide of the granary, and faſtening the crane-rope to it, makes the ſignal for the other to draw it up. Whilſt this is doing, the ſecond ſack is filled, which is wheeled and drawn up in the ſame manner; and this method is purſued till the undermoſt cell is empty.

" If it is neceſſary to ſcreen all the corn at this time, a ſmall ſcreen is fixed under the aperture of the ſecond cell, ſo contrived as to have a box at the back of it, which receives all the duſt, traſh, off-corn, and ſeeds of weeds that paſs through the wires; and this ſcreen is ſucceſſively fixed under every aperture, as the cells are ſucceſſively emptied.

" After the firſt month the corn need be ſtirred in this manner only once a fortnight, and after the firſt ſix months, only once a month, unleſs the weather ſhould prove, in autumn, very hot and damp.

" This then, Sir, is the manner in which I have for ſome years managed my wheat, and find it anſwers very well, the vegetative quality of the corn being preſerved in full vigour, and no ſigns being diſcoverable in it of a tendency to fermentation.

" My country hovel is at ſome diſtance from London, in a retired quarter, conſequently unnoticed; and there being but little probability of this eaſy method's being ſufficiently known by my practiſing it, is the reaſon of my troubling you with this long letter, flattering myſelf that by your means it may make a proper appearance in public. Had vanity been my predominant paſſion, I might have preſented it to the ſociety in perſon, which as a member I had an undoubted right to do; but this would have been encroaching on my beloved obſcurity: to you, therefore, Sir, do I truſt this child of my invention; and if in your hands he can be trained ſo as to be of public utility to my country, my every purpoſe is fully anſwered.

" I forgot to obſerve, that I have lately ſeen Monſ. du Hamel's methods of preſerving grain, by means of cheſts with falſe bottoms and ventilators.

" This method may in ſome caſes be of ſervice, I allow: but I am nevertheleſs of opinion, that corn cannot be properly preſerved, unleſs the whole bulk of it be frequently ſtirred, which by du Hamel's method is not done: could the current of air be equally diſtributed over the whole cheſts, and in due proportion, I ſhould ſtill think it inſufficient to preſerve the corn; and if corn has been kept for ſome time in that manner, I ſhould rather be apt to attribute it to Monſ. du Hamel's firſt drying it on a kiln, before he puts it into the cheſts, than to any regular effect of the ventilators.

" Were I acquainted with this gentleman, I would recommend it to him, to make an experiment of his method in the following manner.

" Let him firſt fill a cheſt with dry corn that has not been on the kiln: another cheſt ſhould be filled with ſome that had been well dried, and a third with the ſame dried corn: let the firſt and ſecond cheſts, at proper intervals, be ventilated, and the third be kept without ventilating, in a dry place. Were this done, I am apt to think, that after ſix months, or a longer time, there would not be found ſo great a difference as ſome may imagine, betwixt the corn which was, and that which was not, ventilated.

" In my method, the expence, as well as hazard of drying is avoided, it being never neceſſary, unleſs when corn is got in very ſoft, in a wet harveſt; and then a common malt-kiln anſwers the purpoſe very well.

" I ſhould have mentioned, that in my method of preſerving corn, when by frequent ſtirrings it is become hard and brittle, it may be laid to the height of three feet, on the floors of the cells, without any danger of damage enſuing; for when it is hard, it is not ſubject to heat and ferment; neither are inſects ſo fond of attacking it.

" I have by this time, perhaps, tired your attention, and to be plain, am not unweary myſelf; ſhall therefore conclude with aſſuring you that I am, Sir,

Your very humble ſervant,

A MEMBER of the SOCIETY."

WHEE, *or* WHEY, a heifer.

WHINS, the ſame with furze. *See the Article* FURZE.

WHISKET, a baſket.

WHITE-CLOVER, a well known plant, and reckoned the ſweeteſt feed of any of the ſown graſſes; and it is of moſt advantage to the farmer, becauſe it is perennial, or laſts a great number of years on the land.

This plant ſends forth roots at every joint, ſo that it thickens, and ſoon makes a thick ſward. When land is to be laid down for paſture, the farmers will reap great profit, if, with about four buſhels of clean ſifted hay-ſeed to an acre, he ſows eight pounds of this clover; but it is to be remarked, that it is never to be ſown with corn.

It may be ſown either in ſpring or autumn; if in ſpring, it may be cut about the latter end of July; if ſown in autumn, the crop will be much earlier. As ſoon as ever the hay is off the land, it ſhould be rolled with a heavy roller. In laying down land with theſe graſſes, it will be proper for the farmer to be very careful that he cleans the land of all ſorts of weeds; and the hay-ſeeds are to be ſown firſt, immediately after which the clover is to be regularly ſcattered. After ſowing, the land ſhould be lightly harrowed, with a ſhort tined harrow, to bury the ſeed; and a few days afterwards, if the weather is dry, it ſhould be rolled, to break the clods, and cloſen it.

It will be good huſbandry, if, after the plants are come up, the farmer ſhould ſend in ſome weeders, to pull up all the tall rampant weeds which might injure the crop, for, if they are ſuffered to ſeed, they will ſoon ſtock the land.

It will be proper to take the advantage of dry weather, and roll the land three or four times, after the plants have attained ſome ſize; for the clover, as is already obſerved, taking root at every joint, the ſward will thereby be greatly thickened.

If a farmer knows his own intereſt, he will ſow ſome of this white clover-ſeed by itſelf, in order to ſupply himſelf with what ſeed he may want, for ſometimes it is very dear. The beſt ſeaſon for ſowing is autumn, upon dry lands, about the beginning or middle of September; but in open, cold lands, much expoſed, a month ſooner is better: all the caution required in this autumnal ſowing is to let the land be very well rolled in the month of October, before the froſts come on, and again in March.

WHITE-SCOUR, a diſeaſe with which ſheep are too often affected, and by which great numbers of them die.

The following medicine has been often given with ſucceſs, provided the ſheep are at the ſame time removed into a dry paſture.

Take a pint of old verjuice, half a pound of common or bay ſalt, dried well before the fire, pounded, and ſifted through a ſieve. Then mix the verjuice with the ſalt by degrees; and add half a pint of common gin, and bottle it up for uſe. When any of your ſheep are ſeized with this diſorder ſeparate them from the flock, and give each of them three large table ſpoonfuls of the mixture for a doſe, repeating it two days after, if they are not better.

WHITE-LANDS, chalky lands.

WILDS, a term uſed by our farmers to expreſs that part of a plough by which the whole is drawn forwards.

WILLOW, the name of a well known tree, of which there are ſeveral ſpecies, ſome of which may be propagated to great advantage, particularly that known by the name of the Norfolk willow, as demonſtrated by the late Mr. North, in an Appendix to a little Treatiſe on Graſſes, publiſhed by him ſome years ago. As this pamphlet may have reached the hands of but few of our readers, and will, now the author is dead, be ſcarcely ever republiſhed; we were perſuaded it merited a place in our work, eſpecially as it may ſerve as an example of a profitable method of cultivating trees of this kind, that may be applied to ſeveral others, only obſerving a due regard to the difference of circumſtances.

Directions for propagating the ſound-growing Norfolk willow.

"This willow (I dare affirm) will prove very profitable to the planter, and of great utility to the kingdom in general. It will grow taller and larger in twenty or thirty years, than moſt other ſorts of trees will in ſixty or ſeventy. It grows very kindly, and great quantities may be propagated at a ſmall expence. A very conſiderable profit from it will come to the planter in five or ſix years after planting: in eight or ten years more another profit will ariſe much larger than the firſt; and at laſt, which will be in about twenty or thirty years after planting, the profit will be ſurpriſing, as I will make it appear in the ſubſequent account.

"In order to begin with this willow-plantation, the land muſt be ſecurely fenced from all kinds of cattle, and muſt be well ploughed or dug in winter, to make the ſurface looſe, and to kill the graſs and weeds. The ſeaſon for planting is from November to April, and ſometimes later. The dryeſt land ſhould be planted firſt.

"One year's ſhoots are beſts for ſets when they are deſigned to make large trees. The ſets ſhould be cut to eighteen or twenty inches long; about eight or nine inches of the thick or lower ends muſl be thruſt into the ground. A ſtrong ſhoot of one years growth will frequently make three or four good ſets, but I would not adviſe cutting any ſets from the very tops of the rods, becauſe they will be too weak to make ſtrong ſhoots the firſt year.

"The proper diſtance theſe ſets ſhould be planted, is about three feet promiſcuouſly. An acre will require about five thouſand. In June after planting, the ſets ſhould be all looked carefully over: and ſuch, as have more than one ſhoot, ſhould be reduced to one, and it ſhould be minded, to leave the uppermoſt and ſtrongeſt. The ſuperfluous ſhoots ſhould be cut off cloſe to the ſet, that the bark may ſooner cover the wound.

"At the ſame time the ground ſhould be hoed over to kill the weeds, and to looſen the ſurface, in order to ſow turnips, which will no ways hurt the ſets, but rather be of ſervice, provided they are properly hoed, and ſet out at good diſtances, and not ſuffered to grow within a foot of the ſets. The winter following, when the turnips are gone, the ground ſhould be dug all over, and, the ſummer after, the weeds cut down with hooks; which is the laſt, and all the labour of cleaning they will ever want. The beſt inſtrument to dig theſe plantations with, is the ſort of broad-trined fork they uſe in Kent to dig their hop-grounds. The price, by the acre, is twelve ſhillings for once digging.

"When theſe ſets have grown four or five years, about three-fourths of them muſt be dug up, in order to leave ſpace for the others to thrive. If they have throve well, in five years they will be above a foot in circumference, and twenty or thirty feet high. Theſe young trees will be very proper for many uſes, as for chair-makers, hoops, gates, hop-poles, &c. and will ſurely be worth three-pence a piece, upon an average.

"From five thouſand ſets which are planted upon an acre, at about three feet apart, certainly three thouſand may be very properly taken away, and the remaining ones will not be left quite ſix feet apart. If theſe young trees are valued at but three-pence a piece, they will be worth thirty-ſeven pounds, but I rather believe, they will be worth more. Eight or ten years after the firſt thinning, three parts in four ſhould again be took up, which will be about one thouſand five hundred; and five hundred or more will be left at about twelve feet apart, which ſhould grow twelve or fifteen years longer, when they will be in fine maturity. The ſecond thinning will be of much more value than the firſt; upon an average, no doubt but they will be worth half a crown a tree at leaſt, as they will be tall and large, and may be put to divers uſes. Many of them will be very proper for maſts for ſmall veſſels, as the wood is light and tough.

"In twelve or fifteen years more, the remaining five hundred trees will be very tall and large, perhaps above ſixty feet high, and five or ſix feet in circumference. The leaſt value one may conceive muſt be twenty ſhillings a tree; ſo that, at the loweſt profit one can ſet upon the produce of an acre of land, planted with this noble willow, in about thirty years at moſt, it will be worth ſix hundred pounds, and all the rent, &c. paid at the rate of twenty ſhillings a year. I really think I have allowed too low prices for the growth, and that it is very probable they will be worth more. The wood of this tree is very white and tough, and without pith or ſap; ſo muſt be very proper for carvers, turners, &c. Boards of this wood are as good for floors, or wainſcoting common rooms, as any other. I am told, by a man of great veracity and judgment, that poſts of this wood, ſet in the ground, will outlaſt all other ſorts, except yew, or heart of oak. He alſo affirms, that there is no tree upon the earth ſo proper for ſhips maſts as this, as it is light and tough, and will not ſplinter, as fir does.

"This tree has oblong, pointed, ſaw-edged leaves of a moſt refreſhing light green: at the bottom of each foot-ſtalk grow two ſmall wings, which almoſt environ the young ſhoots.

"This willow will thrive upon almoſt any ſoil, ſo it be not too dry.

"It is alſo the beſt kind to plant, in large ſets, by the ſides of rills, &c. where they will produce larger lopping, and in leſs time than any other ſort of willow will do.

"If any gentleman, &c. have a mind to make plantations of this profitable tree, it would be well worth their while to lay out the ground in ſome gentle meander-walks; which will be but little extraordinary expence, and, in a few years, will give both ſhade and ſhelter.

"This willow will make the moſt profitable coppice woods, to cut every ſix or eight years, for hop poles, and many other very uſeful purpoſes.

"They ſhould at firſt be planted about two feet and a half apart; and, after five or ſix years, three parts in four ſhould be dug up, and the remainder cut down within ſix or eight inches of the ground, to remain for ſtubs.

"This

"This is alſo one of the beſt ſorts of willow for baſket-makers, as it grows freely, and is very tough.

"In many countries, where firing is ſcarce, this willow would turn to great advantage, merely for fuel; as it will grow into large billets, in three or four years, and will burn very well both green and dry.

"Since I wrote this, a gentleman told me, that he knew of three willow-trees being ſold for fifteen pounds, but he could not inform me what kind they were; I fancy them to be the bright ſwallow-tail willow; for, next to the Norfolk kind, it is the largeſt growing ſort; and beſt for moſt uſes."

Mr. North calls this the Norfolk willow; but that is only a local name, for this tree. It is by ſome called the Hertfordſhire willow, and has had various other names in different places. The deſcription he has given of the leaves, and the firm ſound texture of the wood, without pith or ſap, will, however, ſufficiently aſcertain the ſpecies to thoſe who may not before know it. When he publiſhed this account, he advertiſed, that he would furniſh ſets to any who might want them. As he is very lately dead, who may be his ſucceſſors in his buſineſs, or whether they will continue to provide for the demand of ſets, we are at preſent ignorant. But it would be a matter of regret, that the difficulty of procuring them, ſhould be any diſcouragement to thoſe who may be diſpoſed to make plantations of this tree.

There is an addition, which might be made to Mr. North's plan of deriving an intermediate profit from a plantation of theſe trees, while the principal of them are growing to due maturity. It is this, to leave at the ſecond thinning one tree in the middle of every four, that are intended to grow to maturity; which middle tree will conſequently be at more than ſix feet diſtance from any other, being in the diagonal line of the four. The trees ſo left ſhould be then cut down, within ſix or eight inches of the ground, and ſuffered to ſhoot afterwards as ſtubs or pollards. In which ſtate they will afford hop-poles, billets, twigs, for baſket-work, &c. if cut at proper periods, from ſeven years to every other year, reſpectively to the purpoſes, for which the ſhoots may be wanted. This kind of plantation, of pollards, with tall trees, is not ſo proper in a drier, as in a moiſt ſituation; becauſe the crouding the roots may, in dry ſeaſons, injure the growth of the trees intended to ſtand for wood, where there is a want of moiſture in the ground. But in a wet ſoil, it will rather aſſiſt than retard them; and will be a conſtant ſource of profit during the whole continuance of the plantation.

Other trees may be treated in the ſame manner, allowing for the reſpective differences of each, with very great advantage, in ſwampy and marſhy ground, as in the low parts of meadows, or the waſte of manors; and the plantations will often prove a beauty and convenience in other reſpects. In ſuch caſes the twenty ſhillings per year, allowed for rent in Mr. North's account, may be wholly or moſtly ſaved.

WIND-GALL, a flatulent ſwelling which yields to the preſſure of the finger, and recovers its ſhape on the removal thereof: the tumor is viſible to the eye, and often ſeated on both ſides of the back ſinew, above the fetlocks, on the fore-legs; but moſt frequently on the hind-legs; though they are met with in various parts of the body, wherever membranes can be ſo ſeparated, that a quantity of air and ſeroſities may be included within their duplicatures.

When they appear near the joints and tendons, they are generally cauſed by ſtrains, or bruiſes on the ſinews, or the ſheath that covers them; which by being overſtretched, have ſome of their fibres ruptured; whence probably may ouze out that fluid which is commonly found with the included air: though where theſe ſwellings ſhew themſelves in the interſtices of large muſcles, which appear blown up like bladders, air alone is the chief fluid; and theſe may ſafely be opened, and treated as a common wound.

On the firſt appearance of wind-galls, their cure ſhould be attempted by reſtringents and bandage; for which purpoſe let the ſwelling be bathed twice a day with vinegar, or verjuice alone, or let the part be fomented with a decoction of oak bark, pomegranate, and allum boiled in verjuice, binding over it, with a rowler, a woollen cloth ſoaked in the ſame. Some for this purpoſe uſe red wine lees, others curriers ſhavings wetted with the ſame, or vinegar, bracing the part up with a firm bandage.

If this method, after a proper trial, ſhould not be found to ſucceed, authors have adviſed the ſwelling to be pierced with an awl, or opened with a knife; but mild bliſtering has in general the preference given to theſe methods; the including fluids being thereby drawn off, the impacted air diſperſed, and the tumor gradually diminiſhed. A little of the bliſtering ointment ſhould be laid on every other day for a week, which brings on a plentiful diſcharge, but generally in a few days is dried up, when the horſe may be put to his uſual work; and the bliſtering ointment renewed in that manner once a month or oftener, as the horſe can be ſpared from buſineſs, till the cure is compleated. This is the only method to prevent ſcars, which firing of courſe leaves behind, and unleſs ſkilfully executed, too often likewiſe a fullneſs on the joint, with ſtiffneſs; the mild bliſtering oinment, where the ſublimate is left out, is the propereſt for this purpoſe. *Bartlet's Farriery, p.* 276.

WIND-ROW, the green parts, or borders of a field, dug up, in order to carry the earth on the land to mend it; ſo called becauſe it is laid in rows, and expoſed to the wind.

WINE, a general name given to any briſk, agreeable cordial liquor drawn from vegetable bodies and fermented, particularly that procured from the juice of the grape. *See the article* FERMENTATION.

One and the ſame kind of grape proves greatly different in taſte and flavour, according to the climate and expoſure to the ſun. In cold countries the vine, if it grows at all, never ripens its fruit; and even in France and Italy it is conſtantly obſerved, that the grapes produced on the ſouth ſides of hills are notably ſweeter than thoſe which grow on plane grounds. Among the Tockay wine-hills, there is but one which directly fronts the ſouth, and the advantage of its ſituation are not a little remarkable: from the extraordinary ſweetneſs of its grapes, it is called the ſugar-hill. It affords the moſt delicious of all the Hungarian wines, and is appropriated to the uſe of the imperial family.

In very warm dry ſeaſons, the grapes at the bottoms of the hills are beſt; in warm and moiſt ones, thoſe at the top; ſuch as grow in the mid-region being always good. In dry ſummers, the grapes are ſweeteſt, but leaſt juicy: in rainy ones they abound with juice, which proves proportionably weaker and more dilute. Froſts in autumn promote their ripening; but froſt ſucceeding heavy rains makes them apt to burſt and ſhed their juice.

The

The grapes in America are remarkably apt to burſt; which Mr. Miller imputes, either to the too great moiſture of the air in that country, or to their receiving too much nouriſhment from its over rich ſoil. But gentlemen of America think that their air, except in marſhy places, is drier than ours; and are therefore of opinion, that the burſting of their grapes is not owing to the too great moiſture of the air. If it proceeds from too much nouriſhment, the remedy would ſeem to be eaſy, by training up a great number of branches to conſume that nouriſhment. Others, perhaps with more reaſon, impute their burſting to their ripening too early, while the heavy rains, frequent in autumn, continue to fall. In this caſe, they may be raiſed againſt lofty trees, as was the method of the ancient Romans, and as ſtill is the practice in many parts of Languedoc and Provence. The reflection of the heat, from the earth, would then be leſs, and the leaves of the trees would ſhelter the grapes from the ſun. By this means, being later before they fill, they would not be ſo apt to burſt; and as the latter end of the autumn is generally fair, they may then have an opportunity of coming to their full maturity, without the danger of burſting. Or if it be thought more adviſable to quicken their ripening, the warmeſt ſoil and ſituation ſhould be choſen for the vines, and they ſhould be kept low.

A due degree of maturity is eſſentially neceſſary in every kind of fruit, the juice of which is to be made into wine; becauſe the juice of unripe fruit is a rough acid liquor, which cannot be made to undergo a vinous fermentation, without great difficulty. In ſome inſtances, as in verjuice, it will remain in the ſame ſtate for years together. Nor is there leſs danger from the fruit's being over ripe; becauſe the leaſt taint or putrefaction will, as before obſerved, run through the whole proceſs of the wine, in ſpite of every art that can be uſed to correct or remove it.

When a conſiderable portion of the grapes have attained their full maturity, theſe ſhould be gathered with great ſkill and care; leaving the unripe for a future gathering. Moſt vintagers make it an almoſt general rule, to gather their grapes at a certain ſtated time, according to the cuſtom of the country, without attending to their various degrees of ripeneſs; therein imitating other ruſtics, who ſeldom vary their operations as the ſeaſons vary. Thus, in ſome countries they make it a general rule, to gather their grapes when dry; and in others they as carefully gather them when they are wet with dew. In both, the circumſtances of the ſeaſons ſhould perhaps vary this cuſtom: for example, when a warm kindly ſeaſon has brought the grapes to a due maturity, ſuch juice wants no addition; and if, on the other hand, the dryneſs of the ſeaſon ſhould have thickened their juice too much, the dew may remedy that defect. If a cold or rainy ſeaſon has prevented their ripening thoroughly, and they ſtill continue in an acid watery ſtate, ſurely the warmeſt and drieſt hours ſhould be choſen for gathering them.

In ſome places, the grape is concentrated or rendered richer, by ſuffering it to remain on the tree till great part of its watery moiſture has exhaled; the ſtem of each cluſter being cut half through, when the fruit is ripe, to prevent the afflux of any freſh juice, from the plant. The ſweet Hungarian and Spaniſh wines are made from grapes that have been thus half dried.

In order to make good wine, the grapes of the ſame vine ſhould be gathered at three different times. The firſt gathering ſhould conſiſt of the ripeſt, fineſt and moſt open bunches. They ſhould be cut as cloſe as poſſible to the fruit, the better to avoid the auſtere ſharpneſs and bitterneſs of the ſtalk, and all their rotten or green berries be carefully picked off, or rather cut off with a pair of ſharp ſciſſars. Some are even ſo nice as to cut off the gripes at the end of the bunches, becauſe they are always weaker in quality, as well as leſs ripe, than thoſe which grow higher up on the ſtalk. By this means, they indeed diminiſh the quantity of their wine; but what they do make, is thereby vaſtly improved. An inferior wine is, however, made of the grapes that are ſo cut off. This practice is, indeed, attended with ſome trouble; but it anſwers extremely well, and deſerves to be much recommended, as a means of obtaining at leaſt ſome good wine, in years when, and places where, the grapes do not ripen perfectly. The ſecond gathering ſhould be of the large, cloſe, and leſs ripe bunches; for cloſe bunches never ripen thoroughly: and the third will of courſe conſiſt of the refuſe of the former gatherings; but no rotten grapes ſhould ever be mixed with either. Each of theſe three cuttings ſhould be preſſed ſeparately. It is highly neceſſary always to employ a ſufficient number of gatherers, each of which ſhould be provided with a baſket and knife, and ſhould lay the bunches, as faſt as they are cut, gently in the baſkets, without bruiſing or ſqueezing them: for the more expeditiouſly they are gathered, the finer will be the colour of the wine; and the ſooner they are preſſed the better will be its quality. Women are moſt commonly employed for gathering the grapes, becauſe their labour is cheaper than that of men, and this does not require any great exertion of ſtrength.

This firſt work, which is of the utmoſt importance to the making of good wine, may be ſtill more completely performed by duly attending to the following circumſtance. The fruits of different vineyards are of different qualities: ſome, ſituated on very light and ſtony land, yield exceedingly delicate and high flavoured wine, which ſeldom is ſtrong; whilſt the grapes of vines growing on a richer ſoil, where they receive more nouriſhment, afford a wine which has more body. Both theſe good qualities may be united in the ſame wine, either by mixing the grapes of the different growths before they are preſſed, or by mixing the different wines that have been obtained from them: but the ſureſt way is to mix the grapes, becauſe it is thought that theſe liquors do not eaſily incorporate perfectly after they are made: the weakeſt of them is ſaid to change its colour, and to communicate its defects to the other, inſtead of being mended by the ſuperior quality of that with which it is blended: ſo that, according to many who pretend to have had long experience in theſe matters, the leaſt evil, and that leaſt is a very great one, which can ariſe from thence, is a cloudineſs in the liquor, a ſort of floating lees which will always tarniſh the beauty of its colour, ſpoil the perfection of its taſte, and prevent its ever becoming perfectly bright. This does not happen when the perfect grapes of one vineyard are mixed with the perfect grapes of another: for, from the juices of theſe different fruits preſſed out and fermented together, proceeds an exquiſite, ſound, delicate, fragrant, and bright coloured liquor, which will keep ſeveral years without the leaſt alteration. It is by a knowledge of the good effects produced by a judicious mixture of the grapes of three or four vineyards of different qualities, that the celebrated Champagne wines of Silleri,

Aï, and Hautvilliers, have been brought to the perfection for which they are ſo famed. Every thing that can delight the palate ſeems to be united in them. But this knowledge can be acquired only by many repeated trials and long experience.

One of the ways of making wine in the higheſt perfection of which it is ſuſceptible, is to ſtrip the grapes from off their ſtalks before they are thrown into the vat. By this means all the auſtere roughneſs which the ſtalks would communicate to the liquor is guarded againſt, and the muſt may be ſuffered to ferment, without danger, till the fermentation has ſufficiently opened the body of the fruit. The wine which is thus obtained is the melloweſt, beſt coloured, ſoundeſt, and fitteſt for keeping.

The above directions for gathering and ſorting the grapes are equally proper, whether white wine is to be made, or red; for either of theſe differently coloured wines may be, and generally is, obtained from the ſame grapes, that is to ſay, from black ones. As to the white wine which white grapes yield, it ſeldom has much ſtrength or flavour, ſoon grows yellow, and, for want of body, rarely keeps well even till the next ſummer. All the white wines of Champagne, which look as bright and as clear as cryſtal, are made from the blackeſt grapes, and never preſerve their colour better than when all the plants of white grapes have been rooted out of the vineyard. Formerly, the wine of Aï would hardly keep a year; the thin ſweet juice of the white grapes, of which the quantity was great in the vineyards of that diſtrict, turning yellow, gained the aſcendant, and altered the whole maſs of the wine. But ſince white grapes have been no longer uſed in the white Champagne wines, that of the mountain of Reims laſts ſeven or eight years, and that of the river Marne keeps well for four or five.

The wine of black grapes may be made of almoſt any depth of colour that one pleaſes. They who deſire to have it perfectly white, proceed thus. The gatherers go into the vineyard very early in the morning, and ſelect the fineſt bunches, which they cut as cloſe as poſſible to the fruit, then lay them gently in their ſmall hand baſkets, and when theſe begin to be full, put them, ſtill as gently as can be, into panniers, commonly called dorſers, in which men or women carry them, with the greateſt care not to tumble or bruiſe them in the leaſt, to the end of the vineyard, where they are put carefully into large panniers, with all their bloom, or azure, as it is technically termed, and all the dew upon them. This dew increaſes greatly the quantity of the wine; but at the ſame time it weakens it conſiderably.

If the ſun begins to be a little powerful, the vintagers ſpread wet cloths over the baſkets, whether dorſers or panniers; becauſe, if the grapes ſhould be heated, the liquor drawn from them would be apt to contract a reddiſh teint. If the place where they are to be preſſed is not far from the vineyard, men or women carry the dorſers gently on their backs to the preſs; but if the diſtance is conſiderable, the panniers, into which the grapes are in that caſe put, are loaded upon quiet eaſy going beaſts, which carry them ſlowly, and without ſhaking, to the cellar, where they remain covered and cool. When the heat of the ſun is but moderate, the vintagers continue their work ſafely till eleven o'clock: but when it ſhines ſtrongly, they leave off at nine.

For the making of white wine, of which we now ſpeak, the grapes are thrown, as faſt as the panniers arrive with them, not into the vat, as would be done for red wine, but into the preſs, of whatever form it be, and the firſt preſſing is given immediately. The wine which runs from this preſſing is the moſt delicate of any. The French call it *vin de goutte*, becauſe it rather drops than runs, as but little force is uſed in preſſing it. After this firſt preſſing, which is but gentle, for fear of diſcolouring the liquor, the preſs is raiſed, the ſcattered grapes are thrown up upon the cake, and the ſecond preſſing, called the turning up (*la retrouſſe*) is given. Here the preſs is ſcrewed down with much greater force than before, and if this ſecond running is not quite ſo plentiful as the firſt, though it ſometimes is more ſo, it is at leaſt but little inferior to it in flavour or colour, and preferable in this, that it has a ſtronger body, and will keep a conſiderably longer time. The wine of the firſt preſſing is, however, always ſet apart, if it has been drawn from quite ripe grapes and in very warm weather; becauſe the juice of the fruit then runs very plentifully, and there might be danger of reddening it by mixing it with that of the ſecond preſſing: but this mixing of them is uſeful, and ſometimes neceſſary, on account of the greater ſtrength of the ſecond running when the year is not a warm one, and when the firſt preſſing has not yielded plentifully.

After the two firſt preſſings, the ſides of the cake of grapes are cut down perpendicularly, with a ſteel ſpade, ſo far as they exceed the breadth of the upper part of the preſs which is let down upon the fruit; the grapes thereby ſeparated are thrown up on the top of the cake; and the third preſſing, commonly called the firſt cutting, is given. The juices of this firſt cutting are excellent, to make a perfect liquor; and they may alſo be added to the red wine, if any of this is made ſeparately. A fourth preſſing, a fifth, and ſo on of others, which are called the ſecond, third, and fourth cutting, are given after this; the ſides of the cake being cut down and thrown up each time, till the grapes ceaſe to yield any more juice. The liquor of the cuttings becomes gradually more and more red, becauſe the action of the preſs becomes more and more forcible upon the thin ſkin which envelops the berry, and the particles detached from thence are what render the wine red. Sometimes too the heat of the ſun, or the ſhaking of the fruit in the carriage, are ſo great, and act ſo powerfully upon the outſide of the grapes, that the tinging particles which are in the ſkin of the berries, being let looſe, mix immediately with the juice of the grape at the very firſt preſſing, and then a perfectly white wine cannot be made; but it will be the colour of a partridge's eye, or even deeper. The wine itſelf is not, in fact, at all the worſe for this: but the faſhion is to have it either perfectly white, or of a full bright red.

The wines of theſe different cuttings (as the latter preſſings are called) are collected ſeparately, and afterwards mixed according as they contain more or leſs of the quality that is wanted. Thoſe who have many grapes preſs them at two, three, or even four different times, and collect each of the runnings ſeparately. For the firſt they conſtantly chooſe the moſt perfect grapes, and this wine is always worth a third part more than the ſecond, and ſo on in proportion.

It is eſſential to obſerve that the preſſings for white wine, if it be wiſhed to have it very pale, ſhould be performed as quick as poſſible one after the other, in order that the grapes may not have time to heat, nor the liquor remain long upon the murk. Particular attention ſhould be paid

to this for the two firſt runnings, becauſe they yield the fineſt wine.

Of the ſame black grapes, namely the black moriſons, the pineaus, and the Avernats, with which we have ſeen that white wine is made in Champagne, red wine is made in Burgundy; and indeed the ſame has, of late years, been attempted alſo in Champagne, with no bad ſucceſs; though not ſo as by any means to equal the fine white wines of that country, or the beſt red wines of Burgundy.

As much as the heat of the ſun is avoided by the vintagers who make white wine, ſo much it is ſought after and wiſhed for by thoſe who make red wine. Theſe always chooſe to gather their grapes when the ſun ſhines hotteſt; becauſe they find that its action upon the outſide of the berries produces more effect than ſeveral days ſteeping in the vat would do; for that the grapes then ferment very ſpeedily. As to the reſt, the cautions before directed for gathering the grapes for white wine, in regard to their ripeneſs, the ſorting of them, cutting the bunches off with as ſhort ſtalks as poſſible, clearing them of all damaged, rotten, and unripe berries, &c. ſhould be equally obſerved here. Some expreſs the juice of theſe grapes in the open air, either in the vineyard itſelf or cloſe to it, by throwing the bunches into large tubs, and there maſhing or bruiſing them to pieces, with ſticks, or by putting children into the tubs to tread out their juice. Others carry them home, with care not to bruiſe them by the way, and put them in a vat, in which they are trodden and maſhed. This, in either of theſe caſes, is repeated till the veſſel is full; and after that the broken grapes are let lie in their liquor more or leſs time, according to the heat of the weather, the flavour of the muſt, and the degree of colour that is intended to be given to the wine. During this time, the whole muſt be frequently ſtirred together, the better to raiſe a fermentation, and tinge the liquor with a due degree of red; for it is known by experience, that the redneſs of wine proceeds from the more or leſs intimate mixture of the colouring which is in the ſkin of the grape, with the juice which is contained in the pulpy body of the berry. It is, in fact, chiefly to give this dye to the wine, that the trodden grapes are let lie to ferment in the tub or vat before they are preſſed.

Some adviſe, as a general rule for all red wine, to let the grapes lie in their liquor forty-eight hours; whilſt others, going on in the beaten track of their forefathers, without daring even to ſuſpect that there may poſſibly be errors in the ſtated practice of their country, talk of letting the grapes infuſe during ſeven or eight days, or even longer, and act accordingly: but the authors of the Maiſons Ruſtique, who ſeem to have taken their directions from more judicious and more accurate obſervations, ſay poſitively, that the duration of this infuſion of the huſks ſhould be proportioned, not only to the heat of the weather, but alſo to the natural quality of the grapes, and to the uſual, or intended colour of the wine that is to be made. Thus, for the Coulange wine, which is one of the moſt eſteemed growths of Burgundy, only four hours, or at moſt five, are allowed for the ſteeping of the huſks, unleſs the weather be chilly and rainy, in which caſe they are ſometimes ſuffered to remain all night in the liquor. This is likewiſe, now, the practice of the beſt vintagers throughout the whole province of Burgundy, in moſt parts of that of Orleans, and, in ſhort, in almoſt every part of France where the fineſt, higheſt flavoured, and moſt ſpirituous red wines are made: and the reaſons for it are, that this time is found to be ſufficient to give the wine a duly deep colour; that it is apt to contract a roughneſs from the ſtalks if it remains too long upon them (to guard againſt which, as much as can be, care is taken to pull the ſtalks out with the rake, or ſtick, with which the muſt is ſtirred in the tubs or vat, whilſt others, more cautious, pick the grapes from off them before it is trodden out); and alſo, becauſe too much fermenting of the muſt always renders the wine harſh and coarſe, deprives it of its moſt volatile parts, and the quantity of the muſt is conſiderably diminiſhed by the loſs of what flies off, or is otherwiſe waſted in the fermentation. Others again make it a rule not to draw off their muſt till its head begins to fall. But in this they are evidently wrong; becauſe a great part of the moſt active ſpirits of the liquor is certainly evaporated thereby. It may indeed be true, and probably is, that the liquor which has lain long upon the murk acquires the moſt ſtrength, and is therefore fitteſt for keeping: but at the ſame time it alſo acquires a roughneſs and bitterneſs of taſte, communicated from the ſtones and ſtalks of the grapes, which are far from rendering it the more palatable.

Might not the ſureſt way of judging when the liquor has lain a ſufficient time upon the bruiſed grapes be, to thruſt one's hand pretty deep into the vat, to take from thence a handful of the murk, and to ſmell to it, as the dyers do, to judge of the diſpoſition of their vats? One might then, perhaps, eſpecially with the help of ſome experience, know pretty exactly whether the liquor be ſufficiently concocted, and whether it has acquired colour enough. If it ſmells ſweet, it ſhould be let work a little longer in the vat; at leaſt till it has loſt that ſmell, and has acquired ſo ſtrong a ſcent as to affect the noſe. Then may probably be the right time for drawing it off. A good bodied wine will never taſte of the grape ſtone, if it be taken in its proper degree of the vat; but it will keep found for many years, and be always fit to drink.

To the different ways of managing the muſt is certainly owing, in a great meaſure at leaſt, that ſome people make much better wine than others from grapes of the very ſame ſort, of equal ripeneſs, and of the growth of equally good and well ſituated vineyards. Indeed, for thicker, heavier, and coarſer wines, than thoſe of either Burgundy or Orleans, of which, chiefly, we have now been ſpeaking; ſuch, for example, as the Bourdeaux claret, of which we are ſo fond in this country, and of which the French themſelves do not drink at home, a whole day is frequently allowed for the ſteeping of the huſks, and ſometimes more, before the preſs is recurred to. But as to the rule of letting the grapes lie to ſteep in their liquor forty-eight hours, and much leſs the longer time which ſome recommend and practice; we cannot, for the above reaſons, think it properly applicable to any ſort of wine, unleſs it may, perhaps, be in very cold unfavourable weather, or for ſuch thick, heavy, dark coloured, and very heady wines, as thoſe of Oporto, which, as is well known, are ſcarcely drinkable even here, till age has depurated them and ſoftened their natural roughneſs. It is true, that wine which has fermented long upon the murk may always be beſt for keeping; but it will never be the moſt pleaſing to drink.

We conſequently do not approve of this part of the method of making red wine in Chianti, from whence we may probably judge of the general practice in Italy. When

the grapes there are of a due ripeneſs, and the weather warm and dry, they are cut as ſoon as the ſun or wind has dried up the dew that was on them, and are put into little barrels, commonly called piggins, in which they are carried to the wine vat, on mules if it be diſtant, but between two men if it be near. They are than bruiſed to maſh in thoſe barrels with a club, and thrown directly into the vat, or elſe into a kind of very large hopper placed over the vat, with a grate lengthwiſe, through which the juice, huſks, ſtones, and ſtalks all paſs into the vat, upon their being trodden; and this is continued till the vat is full; when immediately, or ſometimes even hours before it is full, the muſt thus made ferments. By this means the huſks, ſtalks, and ſtones are thrown up to the top of the liquor, where they form a thick cruſt; and this ebullition, which will continue for many days if the liquor be ſtrong, for its duration depends on the ſtrength of the muſt as well as on the temperature of the air, is ſuffered to proceed till the wine is judged to be fit for drawing off. This fitneſs is determined by the palate; and herein conſiſts the greateſt ſkill in the art of making wine. Old practitioners know preciſely, by the colour, ſmell, and taſte of the muſt, the exact time that beſt ſuits their method of proceeding: but it cannot be learnt without great attention, and long experience. The wines of the plains are generally deemed ready for tunning in about ten days, thoſe of the hills in about fifteen, and thoſe of the mountains in Chianti in about eighteen or twenty, or ſometimes more; for in this way of proceeding, the weather has always a very great influence on the ripening of the muſt. When it is judged to be near ready for tunning, thoſe who are ſkilled in thoſe matters taſte it every eight hours. The longer the ebullition is continued, the drier and deeper coloured will the wine be; and the leſs it is continued, the ſweeter and paler will be the liquor.

The vats are proportioned to the quantity of wine that is to be made at one preſſing, and there frequently are ſeveral of them in the ſame vineyard; for the Italians preſs all their red grapes in the open air. The vats on which the hoppers are ſet are covered with boards, and a coarſe linen cloth, the better to prevent the evaporating of the wine, and other accidents.

When the Italians make their ſtrong white wines, or muſcadines, they gather their grapes carefully, and lay them in the ſun for three or four days, or more; always houſing them at night, or at leaſt covering them then ſo that no dew may fall on them. They call the ebullition which theſe undergo in the vat a ſhort one, becauſe it does not exceed five or ſix days; after which they tun up the wine, and ſhift it twice or thrice from one caſk to another, to make it become fine. As to the Verdea or white Florence, as it is called, they draw it off from the vat almoſt as ſoon as an ebullition begins to riſe in it, and has thrown up the huſks, ſtones, &c. ſo as to form a cruſt at top. They then let the ebullition continue for a day and a half, or at moſt two days, in the caſk into which it has been drawn, from which they afterwards ſhift it into another, and in a few hours more into a third and fourth, to check and prevent the fermentation. By this means it is made to retain that ſweetneſs which the ladies in moſt countries are fond of: but wine thus managed never is perfectly fine.

When the muſt has fermented upon the huſks of the grapes in the tubs, or vats, as long as is thought proper, it is poured off from the former into other veſſels, and drawn off from the latter by means of a braſs cock placed about three or four inches above the bottom of the vat, from whence it runs into a receiver, which, as well as that under the preſs, generally is a very large caſk, open at one end, and placed upright directly underneath the cock or channel through which the liquor flows. A bundle of pretty cloſe-tied twigs, commonly of vine cuttings, or of the haulm of aſparagus run up to ſeed, is placed within the vat, before the grapes are put into it to be trodden, cloſe to the entrance of the cock, to prevent the huſks from running into it ſo as to choak it up; and a large ſtone or two is laid upon this bundle, to keep it down. Beſides this precaution to retain the huſks, &c. of the grapes, and prevent their mixing with the liquor that is drawn off, ſome, for greater ſecurity, let their muſt run from the cock through a ſieve, into the receiver, from whence (as alſo from the abovementioned tubs, in the uſing of which the ſame precaution of keeping back the huſks, &c. is carefully obſerved when the liquor is poured out of one into another), it is laded by hand, in bowls, jugs, jets, or pails, and poured into the caſks, through pewter funnels.

After the muſt has been thus poured or drawn off, the murk, that is to ſay, the remainder of the grapes at the bottom of the tubs or vat, is collected together and put into the preſs, where it is ſqueezed very hard, three or four times, in ſhort, till it is perfectly dry, its ſides being cut down each time, and thrown up, as before directed for the latter preſſings of the grapes; and the liquor obtained from thence, eſpecially if the preſs be ſcrewed ſo tight as to crack the ſeeds of the grapes, has a ſtronger body than any of the preceding runnings, but not any part of their fine, high, or delicate flavour. Some, however, mix a little of it with their other wines, to ſtrengthen them, and thereby make them keep the better: but certainly not to mend their taſte.

Others, in whom the ſpirit of œconomy is very prevalent, pour as much water as they think proper upon the murk in the vat, immediately after the muſt has been drawn off. They do this immediately, for fear of the murk's turning ſour, as it would be very apt to do, if they ſhould wait longer. They then ſtir it about, and leave it upon the murk a longer or ſhorter time, according to the heat of the weather, till they find it pretty highly coloured, and judge that it has incorporated all the remaining particles and ſpirit of the wine. They then draw this water off into another veſſel, and carrry the remaining murk to the preſs, where they ſqueeze it till not a drop of moiſture remains in it. The liquor thus extracted is mixed with that which was drawn off before, and is then barrelled. This is principally intended for common uſe, or rather for ſervants: but it muſt be drank in the enſuing winter; for it will turn ſour by the next ſummer. It is briſk and pleaſant enough whilſt it laſts good, and is much preferable to water cyder; though not equal to the refuſe wine, as it is called, of which a vat, or more, is generally made by itſelf, of the damaged, rotten, or unripe black grapes that were left at the laſt gathering, as not being fit for the finer wines.

Another uſe too which the French make of the murk of their grapes after the muſt has been drawn off from the vat, is, to amend ſuch of their wines, whether red or white, old or new, as are deficient in colour or ſtrength.

To

To this end, they empty them out of their caſks into the vat, immediately after the muſt has been drawn off, ſtir the murk up ſo as to mix it thoroughly with them, and then let them remain upon it, at moſt twenty-four hours if it be new-wine, and twelve hours if it be old. When they find that it has taken a ſufficient degree of colour, and that it is not ſweet to the taſte, but agreeable to drink, they draw it off, barrel it up ſeparately, in order to know it again, and then put the remaining murk in the preſs, where it is ſqueezed as dry as poſſible.

As to the white grapes that were rejected at the former gatherings, they are let hang upon the vines till the latter end of October or beginning of November, that they may be a little bitten by the froſt. They are then gathered, and a wine is made of them which is ſold quite warm from the vat, and does well enough to mix with coarſe red wine.

The newly preſſed murk of grapes ſoon contracts a heat; and as it contains many ſpirituous parts, it is then uſed as an effectual remedy for rheumatic pains, ſtiffneſs of the joints, and numbneſs of the limbs. The way of applying it is, to bury the part affected under a heap of fermenting murk.

By the time that the murk has undergone the utmoſt dint of preſſing, it will be as hard as a ſtone: but even then it will yield, when diluted with water, fermented, and diſtilled, a ſpirit which has its medicinal, as well as domeſtic, uſes. Or it makes a good manure for land; particularly, ſay ſome, for vines and for aſparagus.

The too great propenſity to fermentation in hot countries has laid the inhabitants of thoſe parts under the neceſſity of uſing means to retard it: but the method which they practice for this purpoſe renders their wines, as Dr. Neumann juſtly obſerves, ſcarcely deſerving of that name; becauſe they hardly undergo any degree of fermentation at all, and are, in fact, no better than boiled muſt. Several of the Italian wines are of this ſort, and are called by the general name of *vino cotto*, "boiled wine." It is to thin watery juices, extremely prone to ferment, and in which fermentation, when once begun, can ſcarcely be ſuppreſſed till it has run beyond the vinous ſtate, that the proceſs of boiling over a fire is applied. The fermentative quality is thereby reſtrained, and the liquor becomes richer, and continues fit for drinking at leaſt a year or two, though it is never ſo wholſome as the fermented wines. The effects of muſt and of wine upon animal bodies are diametrically oppoſite: for muſt relaxes and liquefies, and, if drank immoderately, is apt to produce dangerous fluxes; whereas perfect wine, on the contrary, corroborates and conſtringes. This the doctor reckons the firſt of three claſſes into which he very properly divides wine, with reſpect to its fermentation.

The ſecond claſs comprehends thoſe wines which have undergone fermentation, but not a complete one. Of theſe there are two kinds. The firſt is the thin ſweet wines; which are no other than muſt partially fermented, or whoſe fermentation is checked, while it can be checked, before the ſweetneſs has gone off. Theſe wines can ſcarcely be kept above a year. Such as the Tyrol, ſome of the Savoy, and ſeveral of the Italian. The ſecond ſort is the ſtrong, full-bodied, rich, ſweet wines, which are generally a mixture of fermented and inſpiſſated muſt; the latter being added to increaſe the richneſs of the liquor, and prevent the fermentation from running beyond its due limits. Theſe kinds of wines greatly heat the conſtitution, and ought to be very ſparingly drank: ſuch are Malmſey, Canary, and ſome of the Spaniſh and Hungarian wines.

To the third claſs belong thoſe wines which have been completely fermented, and have thrown off their groſs matter. Theſe are the moſt perfect wines, and for common uſe the moſt wholſome.

In cold countries, where, for want of the ſun's having force enough to mellow and enrich the juice of the grape, the muſt is thin and poor; ſugar, or dried grapes, ſhould be added to the muſt, to give it a body. Authors name a variety of other ingredients for this purpoſe; but they are uſeful only as they contain a ſaccharine ſubſtance. It is therefore moſt adviſable to uſe good ſugar, which requires no other care than diſſolving it in the juice in the proportion deſired, or found to be wanted. If part of the juice is evaporated by fire, as is ſometimes practiſed, a ferment muſt be added, to make up for the inaptitude to ferment, which experience has ſhewn to be in all juices that have been boiled.

When we here adviſe the adding of ſugar, in particular, we do it on a ſuppoſition of its being the ſubſtance moſt eaſily come at; and alſo becauſe it has been proved by ſome late experiments, that all juices are more or leſs fermentable in proportion to the quantity of ſaccharine matter contained in them.

If the juice is ſo ſour that it will not ferment kindly, no alkaline ſalts ſhould be recurred to, though greatly recommended by ſeveral authors; becauſe they ariſe ſo ſtrong an effervеſcene, that they deprive the liquor of much of its moſt volatile and active principles, and thereby leave it vapid. Inſtead of theſe, ſuch calcarious ſubſtances as will give the leaſt taſte to the liquor, or diſſolve the leaſt in it, ſhould be preferred. Such are, extremely well cleaned oyſter or other ſhells, and hard lime-ſtone or marble reduced to powder. Theſe ſhould not be calcined or burnt; becauſe they would then communicate a diſagreeable taſte to the liquor, and be beſides attended with the diſadvantage of raiſing too great an effervеſcence. Next to theſe, chalk bids the faireſt to anſwer the deſired end. But a caution neceſſary to be obſerved when theſe or any other ſuch like ſubſtances are uſed, is, that the too great acidity of the liquor ſhould be only leſſened; for a certain degree of acidity is eſſentially neceſſary in all wines. If the juice is otherwiſe rich in ſubſtance, and faulty only in being too acid, warmth alone has, in many inſtances, been found to be a ſufficient cure. Madeira, for example, is always harſh, till it has been mellowed by heat: and thus again, ſome gentlemen in England and America, when the juice of their grapes has not fermented kindly, have obtained a very good wine by expoſing the containing veſſels, in a warm ſituation, to the ſun, with an intention of turning it to vinegar. Chemiſts know that all vegetable acids are volatile in certain degrees of heat; and it is highly probable that the effect of this ſummer expoſure may be the evaporation of the acid, and thereby the converſion of the whole into a mild vinous fluid. Inſtances are not wanting, of the rougheſt verjuice being turned to a ſtrong pleaſant cider, or vinous fluid, by means of a warm ſituation accidentally given it. Habit has made a gently acid even deſirable in ſome wines, as in rheniſh.

In ſeveral parts of Germany where the grapes ſeldom come to full maturity, and are therefore gathered ſomewhat green, the makers of wine have iron ſtoves in their cellars, and keep in them a conſtant fire, at leaſt during the time of fermentation. This, by heightening the fer-

mentation, ripens and meliorates the wines, and renders them much more palatable and agreeable than they would otherwiſe be. We have already ſeen that keeping the wines in places conſiderably warmed either by the ſun, or by fire, will have the ſame effect, even ſo late as in the ſummer after the vintage: for acid liquors remain long without either fermenting thoroughly, or putrifying.

As the wines drawn from the laſt gathering of the grapes cannot be ſo perfect as the others, for want of due maturity in the fruit, the people of Champagne and Burgundy have recourſe to the following method, to accelerate their ripening. When the wines have been about three weeks in the caſks, and have been drawn off their firſt lees, they roll them up and down for ſome time, five or ſix times a day, for four or five days running; then two or three times a day, for three or four days; and afterwards twice a day, for about four days; then once a day, for about a week; and after that, once in four or five days. If the grapes were gathered very green, the rolling in this manner is continued, in all, for about five or ſix weeks: but if they were tolerably ripe when gathered, rolling once in four or five days, for about a month or ſix weeks, is found to be ſufficient. This rolling of the liquor in the caſks is intended to ſupply the defect of its firſt fermentation.

It now appears evidenily, from the foregoing account of the practice of making wines in hot and cold countries, that a means to counteract the inconveniences of the climate is wanting in each. If they had proper cellars and vaults, as before obſerved, the too quick and too great fermentation in hot countries might be reſtrained and kept within due bounds; and a proper degree of heat during the fermentation in a cold country, might give the juice that rich mellowneſs which the too weak ſun could not.

The new wines will generally ferment of themſelves, within a few days after they have been put into the caſks. Thoſe that do not ſhould be helped, by putting into them a little of the froth, or yeaſt, which works from the others. The fineſt wines will ferment the ſooneſt: and this fermentation will continue for about ten or twelve days, according to the ſort of the wine, and the ſeaſon of the year.

While the wine ferments, the bung-hole of the caſk muſt be left open, or only covered with a thin linen cloth, to prevent any dirt from falling in: and this cloth ſhould be laid hollow, ſo that the froth ariſing from the fermentation may have room to work off.

When the fermentation is pretty well over, which is known by the froth's ceaſing to riſe ſo faſt as before, the bung may be cloſed down, after filling up the caſk with liquor to within two inches of the top; and a vent-hole ſhould then be opened and left, to carry off whatever may be thrown up by any ſubſequent fermentation. This filling up of the caſk to within two inches of the vent-hole ſhould be regularly performed every two days, for about ten or twelve days running: for the fermentation will continue a conſiderable time, though in a leſs degree; and if the caſks are not kept ſo full as that the foulneſs thrown up by the fermentation may be carried off at the vent-hole, it will fall back again into the wine, and prevent its becoming clear. After filling up each caſk in this manner to within two inches of the bung, for about ten or twelve days, it muſt be filled up to within an inch every fifth or ſixth day, for the ſpace of a month; after which, once a fortnight will be ſufficient during the next three months.

Though the fermentation will be over long before this laſt mentioned time, yet the caſks muſt be filled up once a month ſo long as they remain in the cellar: for as the wine will waſte inſenſibly in them, it will grow flat and heavy, if they are not kept conſtantly filled up. It were needleſs to ſay, that the vent-holes muſt be ſtopped when the fermentation is over.

About the middle of December, the wines may be drawn off from their lees into freſh caſks, for the firſt time; taking care to fill the caſks up, and to place them ſo that they may not be ſhaken or diſturbed until the middle of February, when it will be right to draw them off again into other caſks. If the quantity of lees is then found to be ſo conſiderable as to endanger their contracting a putrid taint by remaining too long mixed with the wine, it may be adviſable to draw it off again after a proper interval of time; or ſometimes it may be neceſſary to repeat this racking even more frequently, though hardly ſo often as is practiſed in Champagne, viz. even twelve or thirteen times in the ſpace of four years; becauſe, though this may render the wine very clear, bright, and pleaſing to the eye, it muſt ſurely diminiſh its ſtrength, and conſequently make it be the leſs fit for keeping.

A leathern pipe, about ſix or ſeven inches in circumference, well ſewed with a double ſeam, to prevent the wine's running out, is, at the diſtance of every five or ſix feet, very tightly bound with ſtrong waxed twine around braſs rings of the ſame dimenſions, made to ſcrew into other rings faſtened in the ſame manner to other ſimilar pipes. The number of theſe pipes may be ſuited to whatever diſtance is found proper or neceſſary: or, when the diſtance between the caſks is always nearly the ſame, the leathern pipe may be made of one ſingle piece, with only a braſs ſcrew-ring at each of its ends. To theſe ſcrews the extremities of the leathern pipe ſhould be fitted, ſo as to ſcrew exactly on or into them, two ſtrong braſs cocks, which are however firſt to be thruſt as lightly as poſſible, by their more taper ends, the one into the uſual tapping place of the caſk which is to be emptied, and the other into the uſual tapping place of that which is to be filled; that is to ſay, each of theſe cocks is to be firmly and cloſely fixed at about two or three inches above the loweſt part of the head of the caſk to which it is applied. It were needleſs to obſerve that theſe cocks muſt be quite ſtrait, the better to complete the communication from one caſk to the other. When every thing is thus prepared, the cocks, being duly fixed in their reſpective caſks, are both opened, and the wine then flows naturally from the full caſk into the empty one, till the liquor becomes of an equal height in each, without in the leaſt diſturbing the lees of the wine in the caſk that is to be emptied. When the wine ceaſes to run ſpontaneouſly, the reſt of it is forced out by means of bellows conſtructed as follows.

Theſe bellows are about three feet long, and a foot and an half broad at their wideſt part. They are made and ſhaped in the common manner to within about four inches of their ſmaller end, from whence the remainder of them is but three or four inches wide. In the inſide of the place where their breadth is thus altered, the air paſſes through a hole of an inch bore; and upon this hole, on the ſide of it that is next the nozzle of the bellows, is a piece of leather, like the valve of a pump, ſo fitted that when the bellows are lifted up to take in freſh air, that valve inſtantly cloſes upon the hole, in ſuch manner that none of the air which has paſſed through this hole, and entered into the caſk, can be drawn back again; but the bellows take in freſh air, by their holes below.

Inſtead of ending with a ſtrait nozzle like other bellows, theſe terminate in a tube or pipe of wood, a foot long, cloſely jointed into their ſmaller end, and there well glued and ſtrongly faſtened by good pegs, in a direction perpendicular to that of the body of the bellows, in order to its conducting the air downward. This nozzle, for ſuch we ſhall now call it in compliance to cuſtom, is round, and about nine or ten inches in circumference over its outſide at the top, from whence it diminiſhes gradually towards its other end, the better to fit it for entering ſome inches in at the bung-hole of the veſſel, and alſo to cloſe up that hole ſo exactly, that no air may get in, or come out, at its ſides. The upper part of this nozzle riſes about two inches above the level of the ſmall end of the bellows, and is there cut ſomewhat flat, that it may be the more eaſily ſtruck with a wooden mallet, and thereby forced the cloſer into the bung-hole of the caſk: and alſo, at about two fingers breadth below the upper part of this nozzle, is nailed an iron ring, thro' which is paſſed an iron hook, or brace, a foot long, by means whereof the bellows are cramped down to the hoops of the caſk: for without this precaution, the force of the air would drive the bellows out of the bung-hole, and the operation of emptying the broached veſſel would not be performed.

It now is eaſy to conceive the manner in which theſe bellows force the remaining wine out of the caſk that is to be emptied: for, upon opening the bellows, the air ruſhes in at the holes in their bottom; and upon ſhutting them, it is forced through their nozzle into the caſk: the valve juſt above their nozzle prevents its returning back; and thus a quantity of air ſufficient to counter-act the weight of the atmoſphere on the wine in the caſk that is to be filled, is eaſily forced into that which is to be emptied.

When the wine is drawn off to within about two or three gallons, a hiſſing is heard in the cock of the then almoſt empty caſk. The cock in the other ſhould then be turned, ſo as to cloſe it, and the pipe of communication ſhould be taken away. That done, all the remaining clear wine is drawn off from the caſk that is to be emptied, but with great care to ſtop when it becomes in the leaſt cloudy. This bright wine is then poured into the bung-hole of the caſk that is to be filled, and the entire filling of it up is completed with ſound wine of the ſame quality as that which has been drawn off. It is then cloſely bunged down; and when this has been done, the cock may be taken out, and a plug put in, with very little loſs of wine. Or, if the owner be ſo curious as to deſire not to loſe any of his liquor, the little air neceſſarily left near the bung-hole may be drawn off with a ſmall hand-air-pump, and then ſcarcely a drop of wine will run out when the cock is drawn.

At every racking of this kind a peg-hole is made in the caſk, if there be not one before, in order to examine the degree of waſting of the wine: for wine waſtes ſenſibly in keeping, how cloſely ſoever the caſk be ſtopped; a part of it tranſpiring through the pores of the wood: but as Dr. Neumann obſerves, it is not the ſpirituous, but the watery part that is thus loſt; for the remaining wine proves ſtronger than at firſt, and the ſtrength continues to increaſe as the quantity diminiſhes. In filling up the veſſels, for it is neceſſary that they ſhould be kept full, care muſt be taken never to mix wines of diſſimilar qualities.

The Hungarian, for example, does not well bear any other wine, particularly rheniſh: for if the ſpontaneous diminution of a caſk of Hungarian wine be made up with rheniſh, though both of them keep extremely well by themſelves, the mixture will preſently ſpoil: and ſo it is of other wines.

The lees in the ſeveral caſks that have been racked off may be collected together, and when their thicker part has ſubſided, a ſpirit may be drawn from the thinner.

Diſtempers ſeldom happen to fermented liquors, but from ſome fault in the manner of managing them. If the fermentation has been duly carried on, the wine racked off the lees before they can contract a putrid taint, and afterwards kept in an equal degree of heat: the wine will anſwer the expectation of the maker. When it is to be tranſported, and thereby neceſſarily brought into a warmer air, brandy is often added, to check the propenſity to a new fermentation. This is alſo ſometimes done to give ſtrength to the wine: but it is not a practice by any means to be recommended.

It is neceſſary for the preſervation of ſome wines, particularly of ſuch as are apt to be frequently on the fret, to fumigate the caſks with burning brimſtone, to which ſome add, perhaps uſeleſsly, vinous ſpirits and aromatic ingredients. The fumes of brimſtone ſtrongly reſiſt fermentation, but wines which are largely impregnated with them cannot be recommended as wholeſome. The colour of red wine is deſtroyed by them. What is called ſtum, is no other than muſt whoſe fermentation has been prevented, or prematurely ſuppreſſed, by fumigation with ſulphur.

The colour of wine is frequently artificial. A pale yellow may be natural, but a fine deep yellow proceeds from an addition of burnt-ſugar, or other colouring matters, or from the oaken caſk in which the wine has been kept. Wine may be naturaly of a pale dilute red; but a deep red is almoſt always the effect of artificial additions, as of the red-woods, elder-berries, bilberries, &c. In France, no ſecret is made of theſe practices, the colouring matters being publicly thrown out after they have been uſed. Turbid wines are fined by a mixture of whites and ſhells of eggs, powdered alabaſter, and iſinglaſs. The uſe of the ſhells and alabaſter is to correct any ſmall degree of acidity that the wine may have contracted: and indeed if we look into the many compoſitions made uſe of by vintners, we ſhall ſee that they are all framed upon this principle; wherefore it would be needleſs here to particulariſe them. If the wine is grown very ſour, the beſt way of correcting it, ſo as to preſerve the ſpirit and flavour, is, by adding a quantity of ſalt of tartar ſufficient to neutralize the acid, juſt before it is to be uſed. It then becomes a pleaſant wholeſome liquor: but if ſalt of tartar is mixed with any fermented liquor long before it is to be uſed, the efferveſcence which it raiſes will deprive the liquor of its ſpirit, and leave it quite vapid. Iſinglaſs is uſed only for clariſying the wine. Weak wines are improved by an addition of ſpirit, particularly before the fermentation is completed, for after this period it is apt to ſpoil the vinoſity. Poor wines are enriched by ſweets, and flavoured by various additions ſo as to emulate the more coſtly: thus elder-flowers give the flavour of Moſelle, and the flowers of the yellow clary will make almoſt any common white-wine reſemble new rheniſh. Even the moſt delicious wines have been imitated alſo without a drop of the juice of any grape; with ſolutions of ſugar, juice of currants, figs, and other fruits.

After the wine, and particularly that of countries where the ſun is not very powerful, has paſſed its fermentation in the vat, and is drawn off into caſks, it will require ſomething to feed upon. To this end, it will be right always to preſerve a few bunches of the beſt grapes, which may be hung up in a room till there be occaſion for them; when they ſhould be picked off the ſtalks, and two or three good handfuls of them ſhould be put into each caſk, according to its ſize.

The French recommend ſtrongly the two following methods; the one for giving additional ſtrength and colour to red wine, and the other for clarifying wines in general.

For the former, a ſound well-hooped caſk is ſet upright on one of its ends, the other end is taken out, and a layer of vine-cuttings is ſpread at the bottom of the caſk, to the depth of about three inches. Some of the fineſt and ripeſt black grapes are then choſen, and their berries are cut off from the ſtalks, as cloſe as poſſible to the fruit, which the utmoſt care is taken not to burſt or damage. The grapes thus ſelected are put gently upon the layer of vine-twigs, and the caſk is filled with them up to the beginning of the bung-hole. Another layer of vine-cuttings is placed gently upon theſe grapes, till it reaches the upper part of the bung-hole, and the caſk is then filled with grapes, culled as before, to within a foot of the top, where another layer of vine-cuttings is ſpread over them, and the head of the caſk is then replaced. The caſk thus prepared is filled with good coarſe red wine, to within three fingers breadth of the bung-hole, that the liquor may have room to ferment without much loſs, and in this ſtate it is carried gently to the place where it is to remain. Great care is taken to keep this veſſel conſtantly filled up with wine of the ſame ſort, both whilſt it ferments, and afterwards as it is uſed: for if the grapes in it were at any time to be left long without a ſufficient quantity of wine upon them, the whole would grow vapid and be ſpoiled. The principal uſe which the vintners make of this liquor, is to ſupply their cuſtomers conſtantly with wine of the ſame taſte and colour, by mixing it with what they ſell.

The other method, which is practiſed only when wine is to be fined very ſpeedily, conſiſts in this. A parcel of very thin chips, the longer the better, or of pretty thick ſhavings, of new but well dried beech, is ſteeped for two days in water, which is changed at leaſt twice a day, the better to take off the taſte of the wood. Theſe chips are then well drained; and after they have been thoroughly dried in the air, as many of them are put lightly into a caſk, of which the head has been taken out for this purpoſe, as will fill it to within about a finger's breadth of the top. The head is then properly replaced in the caſk, ſo as to fit it for holding liquor, and a pint of good brandy is poured in at the bung-hole, upon the chips. After this, the bung-hole is ſtopped cloſely with a bung, and the caſk is rolled about till the chips have imbibed all the brandy. The caſk is then carried to its allotted place, and immediately filled with ſome of the wine that is to be ſpeedily fined. The wine will ſoon be fit for drawing off; and when that is done, the caſk with the chips in it ſhould be filled up again directly, becauſe the chips, like the grapes and wine-cuttings beforementioned, will looſe all their virtue if they are left long without a ſufficiency of liquor upon them.

When the wine that is poured upon theſe chips begins to require a length of time in order to its becoming fine, it is a ſign that they are over-loaded with lees. The head of the caſk is then taken out anew, the chips are waſhed in water till they are cleared of the lees, they are then dried in the air as before, and after being again ſoaked with brandy, or waſhed in perfectly clear wine, they are replaced in their former caſk; after that this alſo has been well waſhed and cleaned, and they continue to anſwer the ſame purpoſe as at firſt.

All the abovementioned practices are innocent enough: but, as Dr. Neumann rightly obſerves, ſome of the dealers in wines have had recourſe to ſuch dangerous artifices as have been pernicious to thouſands. They have ſweetened acid wines by litharge, or other preparations of lead; and impregnated ſweet ones with mercury-ſublimate and with arſenic. Lead is diſcovered in wines by adding a decoction of orpiment made in lime-water. If the wine is genuine, it does not ſenſibly change its colour on this addition, though on ſtanding, a yellowiſh white powder falls to the bottom: but if it has any ſaturnine impregnation, its colour becomes immediately darker, brown, reddiſh, or blackiſh. Arſenic may be detected by a ſolution of lead in aqua fortis; and mercury-ſublimate, by volatile alkaline ſpirits, or by a ſolution of fixed alkaline ſalts.

As to the concentrating of wines by cold, commonly called condenſing or congealing of them, it ſeems to us ſo much a matter of mere curioſity, rather than of uſe, that, though Dr. Stahl has taken the pains to give a full and accurate account of the manner of performing this proceſs, by which the wine is not only freed from its ſuperfluous humidity, ſo as to be greatly diminiſhed in bulk, and of courſe rendered more convenient for tranſportation, but alſo, ſay the advocates for this practice, infinitely enriched and ennobled in its quality, and rendered ſo much more perfect and durable, as to be from thenceforth unalterable by any accident or changes of the weather (for by this means "the philoſophic ſpirit of the wine," to uſe the language of the adepts, is obtained).

"When wines, ſays Dr. Neumann, are expoſed to the action of a freezing air, a part of their water congeals, and the unfrozen part proves proportionably ſtronger and more ſpirituous. By repetitions of this proceſs, firſt pointed out by Paracelſus, and ſince carried to a greater length by Stahl, the beſt wines are reduced to about one ſixth of their original volume. Wines thus concentrated or freed from their redundant phlegm, are no longer the delicate liquors they were before. They are too unpleaſant, as well as too ſtrong, to be drank by themſelves; and when mixed with other wines, they communicate to them alſo a diſagreable taint. The phlegm which congeals retains a part of the truly vinous matter, as appears from its being convertible into vinegar; but this phlegm, mixed with the unfrozen wine, does not reſtore its pritine qualities: both the phlegm by itſelf, and the mixture, ſoon corrupt. When once the principles of wine are ſeparated from one another, no art can reproduce wine by joining them together again. When barely the inflammable ſpirit has been diſtilled off, the addition of that ſpirit to the reſiduum does not reſtore its vinoſity. The reſiduum itſelf often ſuffers a new ſeparation upon this addition, its tartareous parts precipitating."

When the wine is of an age at which it uſually is bottled, care ſhould be taken to examine whether it be ſufficiently

ciently bright; becauſe a natural brightneſs is the moſt certain indication of the liquor's having undergone a due fermentation, and conſequently of its being rendered moſt wholeſome. If any ſmall degree of cloudineſs is obſerved in it, the whites of eggs will eaſily remove that imperfection; and if it inclines to tartneſs, the ſhells of the eggs ſhould be mixed with their whites: but if the degree of cloudineſs is thought to be greater than the whites of eggs will cure, recourſe is had to iſinglaſs, the quantity of which ſhould be proportioned to the quantity of the liquar, and to its degree of foulneſs; for wine that becomes bright of itſelf does not need any. The proper way of uſing the iſinglaſs, is to diſſolve it over the fire in ſo much water as will form it into a jelly; then to dilute it ſufficiently with ſome of the ſame wine as it is intended to clariſy, afterwards to ſtrain it through a flannel bag, and finally to pour it into the caſk, and ſtir it well about with a whiſk that reaches only to about half way down the caſk. For wine that is very tart, the proper corrective is powdered marble, alabaſter, or un-burnt lime-ſtone, as before directed.

A quite faſhionable gentleman would hardly have vouchſafed, a few years ago, to taſte a glaſs of Champagne which did not ſparkle or froth ſtrongly: but that notion of its excellency is now pretty much laid aſide. Opinions have been ſo greatly divided in regard to the cauſe of this ſparkling, ſome aſcribing it wholly to the force of drugs uſed for that purpoſe by the dealers in this wine; others imputing it to the un-ripeneſs, or, as ſome call it, the tartneſs of the wine, becauſe, in fact, moſt of the wines that do ſparkle and froth are extremely tart; and others again attributing this effect to the influence of the moon, according to the times of bottling theſe wines, that we cannot do better than copy here the ſubſtance of what the authors of the Maiſon Ruſtique have ſaid on this ſubject.

"It is true that many dealers in wine, ſeeing how immoderately fond moſt people were of this ſparing liquor, did often put into it alum, ſpirit of wine, pigeon's dung, and many other drugs, to make it froth exceedingly; but it is certain, from experience, that the bottling of it at any time between the vintage and the month of May, will alſo make it froth. Some pretend that it froths moſt when it has been bottled neareſt to the time of gathering the particular ſort of grapes of which it was made; but many deny this. There is no time of the year in which it froths more than at the end of the ſecond quarter of the moon in March; and that without any artifice at all. One may always be ſure that the Champagne wine which has been bottled between the tenth and the fourteenth days of the ſame moon will froth perfectly. This has been proved by ſuch reiterated experience, that it cannot be doubted. It is, however, proper to obſerve, that the wine does not froth immediately after its having been boiled. It muſt have been at leaſt ſix weeks, and often two months in bottles, before it will froth well. If it has been tranſported to any diſtance, it muſt be let reſt for a month in the vault, eſpecially in ſummer, to recover itſelf.

"But as the Champagne wines, and particularly thoſe of the mountain of Reims, are not in general ſufficiently ripe for bottling at the abovementioned time, but ſtill retain too much tartneſs, or hardneſs, if the ſeaſon has been cold and moiſt; or too much ſweetneſs, if it has been hot; the ſureſt and beſt way to have exquiſite wine which ſhall froth perfectly, is not to bottle it till the riſe of the ſap in Auguſt. Experience has certified, that it froths exceſſively when bottled between the tenth and the fourteenth of the moon in Auguſt: and as it will by that time have loſt its too great tartneſs, or its over great ſweetneſs, one may be aſſured that the wine which is bottled then will be the ripeſt and moſt frothy.

"Another experiment has been tried, which is, not to bottle the Champagne mountain wine till the ſpring of the ſecond year, that is to ſay, eighteen months after it has been made; and it has been found to froth ſufficiently, though not above half ſo much as that which was bottled while the ſpring-ſap of the preceding year was riſing. It is not thought that the river wine, which has leſs body than that of the mountain, can froth ſo much in the ſecond year.

"They who would have Champagne wine that does not froth at all, muſt bottle it in October or November of the year after the vintage. If it be bottled in June or July, it ſtill will froth a little, though but very little.

"As theſe wines, eſpecially in their firſt year, work continually in the cellars and vaults, and ſtill more in bottles than in caſks, according to the different ſeaſons and the different impreſſions of the air; it is not ſurprizing that the ſame wine, particularly the new, ſhould ſometimes appear different to the taſte. A wine, for example, which is fit for drinking in January and February, ſhall ſeem hard in March and April; becauſe of the riſing of the ſap which then agitates it: and this ſame wine, after ſeeming to be perfectly ripened in the next June and July, ſhall again have, in Auguſt and September following, a hardneſs which could not be perceived in either of the two preceding months; becauſe the riſing of the ſap in Auguſt will have increaſed the motion of its parts, or, in other words, have ſet it on the fret. Thus the ſame Champagne wine, of the firſt year, if it be of the river growth, and frequently that of two years old if it be of the growth of the mountain, will appear more or leſs ripe or mellow, more or leſs exquiſite, more or leſs forward, according to the different motions it receives from the different impreſſions of the air, which vary moſt ſenſibly in the different ſeaſons of the year."

What is here implied, though perhaps not quite clearly expreſſed, is, we apprehend, the true cauſe of the ſparkling or frothing of wine; namely, its not having been perfectly fermented, and conſequently not had a thorough aſſimilation of its conſtituent parts. The want of this certainly makes it fret in the bottle: and accordingly we ſee, that, the better to ſecure its ſparkling, the people of Champagne bottle it in the very ſeaſon when it is moſt likely to be on the fret; viz. at the time of the weather's turning from cold to warm. Several other cauſes may likewiſe put wine on the fret, and among theſe a principal one is the want of cellars in which an equal temperature of the air is preſerved all the year round. This, and the imperfectneſs of the fermentation of the liquor, are undoubtedly the real cauſe of the ſparkling or frothing of wine.

As a general rule, if it be intended that the wine ſhould not froth, the beſt time for drawing it off, whether into bottles, or into caſks, is when the weather is extremely fair and clear, the barometer high, and, of choice, during a northerly wind; becauſe the air is then cooleſt, and the wine leaſt apt to be on the fret. By inverting theſe rules, and drawing off the wine in warm damp weather,

when

when the barometer is low, and the wind ſoutherly; what is bottled at this time will froth; for wine in the caſk is always cloudy then, and conſequently diſpoſed to fret.

It may not be uninſtructive, and certainly cannot be unentertaining to our readers, if we copy here Dr. Neumann's account of, and curſory remarks on, the principal wines that are drank in Europe. "1. The Madeira iſlands, and Palma, one of the Canaries, afford two kinds: the firſt called Madeira Sec; the latter, which is the richeſt and beſt of the two, Canary or Palm Sec. The name Sec (corruptly written Sack) ſignifies dry; theſe wines being made from half dried grapes. There is another ſort of Sec wine, inferior to both the foregoing, prepared about Xeres in Spain, and hence called, according to our orthography, Sherris, or Sherry. 2. The wines of Candia and Greece, particularly the latter, are of common uſe in Italy. Malmſey was formerly the produce of thoſe parts only, but is now brought chiefly from Spain: it is a ſweet wine, of a golden or browniſh-yellow colour: the Italians call it *Manna alla bocca e balſamo al cervello*, "Manna to the mouth and balſam to the brain." Zant and Cephalonia ſend alſo to Venice ſome good, and no ſmall quantity of indifferent wines: almoſt all the wines indeed made uſe of in the Venetian territories come from Greece and the Morea; of which there are ſome ſorts ſo bad, and ſo cheap, that large quantities are made into vinegar for the preparation of ceruſſe. 3. Italy, not Greece, produces the *vino Greco:* this is a gold-coloured unctuous wine, of a pungent ſweetneſs, the growth of Mount Veſuvious, greatly ſophiſticated by the Neapolitans. In the neighbourhood of Veſuvious is made the Mangiaguerra wine, as alſo a thick blackiſh one called Verracia; and at the foot of the hill, the delicious *vino vergine*. The Italians apply this laſt name likewiſe to all the other wines made without preſſure. The kingdom of Naples affords the Campania or Pauſilippo and Muſcatel, the Surentine, Salernitan, and other excellent wines, as alſo the Chiarello, much drank at Rome. But the principal of all theſe wines is the red, fat, ſweet, and gratefully poignant one, called *Lachryma Chriſti*. The eccleſiaſtical ſtate produces the light, pleaſant Albano; and the ſweet Monteſiaſcone, a yellowiſh not very ſtrong wine, which comes the neareſt to good Florence, but does not keep well; together with ſeveral of leſs note, as the Nomentan, Monteran, Velitrin, Prænetic, il Romaneſco, d'Orvieto, &c. 5. In Tuſcany are the excellent white and red Florence; the celebrated, hot, ſtrong red wine of Monte Pulciano; the Montalneo, Porte Hercole, &c. But along the coaſt of the Adriatic, at Ancona, Rimini, Peſaro, and as far as Bologna, one meets with exceeding bad wines, chiefly of the boiled unfermented kind, heavy, diſagreeable, and unwholeſome. 6. In Lombardy alſo there is abundance of bad wines: the Modeneſe and Monſerrat are tolerable; the Marcemino, produced about Vicenza and Padua, pretty good. The other wines moſt commonly drank in that province are the Breſcian, Veroneſe, Placentine, Lumelline, and Pucine; and in the Genoeſe, the Vino di monte vernaccia, vino amabile or vino di cinque terre, and Vino razzeſe. Between Nizza and Savona is produced an incomparable Muſcadine; near Aquileia is the Roſatz, and near Pavia the Vino Piccante. 7. Piémont, and part of Savoy, have excellent light wines. 8. The Sicilian, Sardinian and Corſican wines are alſo good: the firſt, as particularly the Catanian, Panormitan, Meſſinian, and Syracuſan, are accounted the beſt, and are chiefly bought up by the knights of Malta. 9. Moſt of the Spaniſh wines are compoſed of fermented or half fermented wine, mixed with inſpiſſated muſt and variouſly manufactured, or of an infuſion of dry grapes in weak muſt. No wines freeze more difficultly than the Spaniſh; theſe abounding both with unctuous matter and with inflammable ſpirit. The principal of them are, the Alicant, which is a thick, ſtrong, very ſweet, and almoſt black as well as nauſeous wine; Sherry, Spaniſh Malmſey, Malaga, commonly called Mountain, and what is ſimply termed Spaniſh wine. Theſe, at leaſt, are the ſorts moſt generally imported here: but in Spain itſelf there are many more, ſuch as, the Tarragon, Salamanca, Cordova, Galicia, Andaluſia, ſundry baſtards, vino de toro, &c. 10. In Portugal there is plenty of red Port, a cheap but not a very excellent wine, drank in large quantities in England, and often dreadfully ſophiſticated. The beſt vino tinto, a blackiſh red wine uſed by the coopers for colouring other wines, is ſaid by ſome to be the produce of Portugal. So largely do the Portuguze deal alſo in Madeira, that their king receives yearly twelve thouſand pipes of this wine by way of tythes. 11. In France, there is a great variety of wines; of which the ſtrong, ſweet, full-bodied, ſpirituous ones are called *Vins de liqueur*. There is ſcarcely a province in France that does not produce wine: Languedoc and Provence afford the ſweeteſt; and the ſame provinces, with Champagne and Burgundy, the ſtrongeſt. The wines of the northern parts of that kingdom, as Picardy and Bourdeaux, are the worſt; and thoſe about its middle, as Paris and Orleans, of a middling kind. The moſt celebrated of the French wines are thoſe of Champagne and Burgundy, the Cote rotie, St. Laurence, Frontignac, Muſcat de Lion, Cahors, Hermitage, Grave, &c. 12. In Swiſſerland, the beſt are the Neuſtchatel, Velteline, La cote, and Reiff wines. The Velteline ſtraw-wine, ſo called from the grapes being laid for ſome time upon ſtraw before they are preſſed, is particularly celebrated. 13. The dry-grape wines of the Upper-Hungary are in general excellent, and greatly ſuperior to thoſe of the Lower. They have a delicious aromatic ſmell and taſte, a notably diaphoretic, and corroborating virtue, and when drank freely occaſion no head-ach, heavineſs of the limbs, or other inconveniencies. They do not eaſily become vinewed even in open veſſels; and retain their ſweetneſs and agreeableneſs for a length of time, though they loſe a little of it from year to year. 14. Among the German wines, the Tyrol are very delicate, particularly thoſe of Tramin and Etſch; but they do not keep. 15. Good Auſtrian wine is not to be rejected. Thoſe of Kloſter-Neuburg and Broſenberg are accounted the beſt, and, in the opinion of ſome, excel in taſte that of Edenburg in Lower-Hungary. There are alſo good wines in ſeveral other parts of the imperial dominions. 16. In the Palitinate, the beſt wine is that of Worms, eſpecially the ſort called woman's milk; and next to this, thoſe of Edinghoff and Ambach. 17. Among the more eſteemed German wines are to be reckoned alſo Rheniſh, Mayne, Moſelle, Neckar, and Elſaſs. A certain writer calls the Rheniſh made in Hockheim (hock) the prince of the wines of Germany. 18. The Bohemian, Sileſian, Thuringian, Miſniam, Naumberg, Brandenburg, and other German wines, are generally inferior to the foregoing. Some however, of thoſe of Miſnia and the Marche, made from ripe picked grapes, have this advantage, that they are greatly meliorated by age, ſo as to be preferred by many to the Rheniſh, Neckar, and

Franconia

Franconia wines, and frequently mixed with other of greater note. The tartiſh German wines keep the longeſt of any: ſome of them have been kept two or three hundred years; and in Straſburg there is a caſk of it fourteen hundred years old, and many above ſeventy; the wine being occaſionally racked off into ſmaller and ſmaller caſks, that the veſſel may be conſtantly full. Theſe very old wines are preſerved rather for curioſity than uſe, as they not only grow too ſtrong for drinking, but at laſt quite diſagreeable. The beſt are thoſe of a middle age, from twenty to about fifty years."

We cannot cloſe more properly, than with the above quoted excellent chemiſt's definition of the characters of good wine.

"The goodneſs and wholeſomeneſs of wines are judged of, from their being bright, clear, and ſparkling in the glaſs; of an agreeable reviving ſmell and taſte; leaving, when held in the mouth for ſome time, a ſlight ſenſe of aſtringency; being moderately ſtrong and ſpirituous; paſſing freely by urine; exciting appetite; producing a gentle ſweat in the night; keeping the belly open next day; without being followed by any head-ach, heavineſs of the limbs, or other uneaſineſs. Such a wine, moderately uſed, is a very valuable cordial. The ſweet rich wines are either new, or very ſtrong and fiery: they heat the body much more, and, if drank to any degree of exceſs, their effects continue much longer than thoſe of the thinner wines, which contain an equal quanty of ſpirit. The red wines, in general, have the greateſt aſtringency."

The following directions for making domeſtic wines, taken from the Muſeum Ruſticum, will, we are perſuaded, be agreeable to our readers.

"As to the art of making wine, I think the rendering it more generally known, and practiſed here, may not only afford a convenience with regard to expence, and a ſecurity with regard to health, to private perſons; but an advantage to the public, in the balance of trade: a principle, at preſent, overlooked: though, in a ſhort time, it will probably be ſeen in a more intereſting light.

"Among the various articles of foreign luxury, wine certainly makes one of the moſt capital; and yet, what with the taking ſuch extreme great quantities, as oblige us to receive, as well the product of inferior, as good vintages; and what with adulteration, as well practiſed before the wine is imported hither, as after; we in general drink very indifferent natural wines, or very exceptionable artificial mixtures of liquors, called ſo. Though for theſe, we either pay great annual ſums to foreign countries, or to thoſe, who make it their buſineſs to impoſe upon us at home.

"This is the more to be regretted; becauſe we have it in our power wholly to avoid it: and, by a little attention and trouble to provide ourſelves with wine, that is ſuperior in flavour, cordial effect, wholeſomeneſs, and every other quality, with a ſaving of at leaſt fifty or ſixty *per cent.* of the expence. The means, by which, I ſuggeſt it to be in our power to do this, is, by the domeſtic production of wine in our own families: which, were the art well known, and the advantages, as I have here enumerated them, well underſtood, could not ſurely fail to be a much more general practice than it is at preſent.

"It may be ſaid to appear from experience, that wine thus made here, is not ſo good as the foreign: and that, we find, in the inſtances of thoſe, who have tried to introduce it, the ſucceſs is not equal to my repreſentation. To this, I anſwer, that experience has verified what I advance, in the few inſtances of thoſe, who have made domeſtic wine with ſkill; and kept it to be of a due age. without which, even foreign wine would not be good But the reaſons, why greater numbers do not ſucceed, is the want of knowledge; a ſordidneſs, with reſpect to expence; or the drinking the wine before it be fit; which is almoſt univerſally the caſe. For, where this art has been practiſed without any of theſe diſadvantages, ſuch wine has been produced, as not only has equalled the foreign, in all general good qualities; but has even been miſtaken for ſeveral of the moſt valuable kinds, even by the moſt ſkilful judges.

"The want of knowledge in the art of making domeſtic wine, being, therefore, one principal cauſe of the neglect of doing it more frequently, I ſhall here endeavour to remove it, by furniſhing ſuch inſtructions, as can ſcarcely fail to enable any attentive perſon to practiſe it, with eaſe and certainty. And, I am perſuaded, that, to middling people, eſpecially thoſe living in villages and places remote from ſea-ports, where it is difficult to procure even indifferent wine in ſmall quantities, I ſhall do a material kindneſs: though the advantage of making domeſtic wines is, by no means, confined to ſuch perſons, or ſituations; but even all others might find their account in it, both with reſpect to expence and health.

"I will, therefore, firſt give a recipe for making the moſt perfect wine, that can be produced, by compoſition, in this country. By compoſition, I mean, ſuch as is not made of the ſimple native juice, of any one kind of fruit. But this kind is, indeed, in a great degree native, as the water added to the dry fruit is only, in fact, the reſtoration of what evaporated in the drying and ripening the fruit: and the produce of this proceſs is, therefore, in reality, a natural wine, and ſuperior to any, that can be made of the native juices of the fruits of our country; or perhaps equal to the beſt of thoſe of any other. This recipe will ſerve, alſo, as a baſis, for the ſhowing afterwards how other, and cheaper kinds, may be made.

"Take thirty gallons of ſoft water, either rain, or river water. It ſhould be obtained in as clear a ſtate as poſſible, but boiling is needleſs. Put this water into a veſſel, at leaſt, one-third bigger than will contain that quantity: and then add to it one hundred weight of Malaga raiſins, groſsly picked from their ſtalks. Mix the whole well together, that the raiſins may not remain clotted in lumps: and then cover it partly, but not intirely, with a linen cloth: and let it ſtand in a warm place, if the ſeaſon be not hot. It will ſoon begin to ferment; and muſt be well ſtirred about, twice in twenty-four hours, for twelve or fourteen days. It muſt be then examined, by the taſte, to try if the ſweetneſs be nearly gone off: and if that be found ſo, and the fermentation be greatly abated, which will be perceived by the raiſins beginning to lie quietly at the bottom, the fluid muſt be ſtrained off; and preſſed out of the raiſins, firſt by the hand, and afterwards by a preſs, if ſuch be eaſily procured. But, if there be no preſs, two boards may be uſed with the aſſiſtance of a large weight, or other ſtrong compreſſive force; which muſt be continued as long as any fluid can be made to drop from the maſs. The fluid, thus ſeparated from the ſkins, or marc of the raiſins, muſt be then put in a good ſound wine caſk, well dried and warmed, together with eight pounds of Liſbon ſugar, and a little yeaſt: but ſome part of the liquor muſt be kept out, to be added, from time to time, as the abatement of the

fermentation, that will come on again, may admit, without the wine riſing out of the caſk. In this ſtate it muſt continue for a month, with the bung-hole open: and then, the whole of the liquor kept out, having been now put in the veſſel, muſt be cloſely ſtopped up; ſo that no air may enter: and in this ſtate it muſt be kept for a year, or longer. At which time, it may be bottled off.

"This wine may be drunk, and will be very good at the end of a year and half: but it will be much better, if kept longer: and will improve for four or five years. When it has a proper age, it will equal any of the ſtrong cordial foreign wines: and may, by the addition of proper ſubſtances to flavour and colour it, be made to reſemble them.

"This is the moſt perfect kind, of what may be called artificial wine; but others may be made cheaper. There are two methods of making a ſaving in the expence. The one is, to ſubſtitute, inſtead of the whole quantity of raiſins here directed, a greater proportion of ſugar: leaving out four pounds of raiſins for one of ſugar added: or the quantity of both ſugar, and raiſins, may be diminiſhed; and a proportion of clean malt-ſpirits added, when the bung of the caſk is cloſed up. The uſe of diſtilled ſpirits, in this manner, is not ſo objectionable, as it may at firſt appear to perſons, who are not acquainted with theſe matters. For ſuch ſpirits will loſe their fiery quality, and be rendered ſoft and mellow, by their incorporation with the oily part of the wine. And there is nothing more certain, than that the practice of uſing them is general in the preparation of all the foreign wines, for our market: and moſt particularly thoſe ſtronger kinds, which are moſt eſteemed by us.

"Any other kind of large raiſins, which are cheap, may be uſed, as well as the Malaga: and the thinner the ſkins, and the ſweeter the pulp, the ſtronger will be the wine.

"It has been practiſed formerly to bruiſe the raiſins; but it is unneceſſary with reſpect to the common ſorts, as they will ſoon burſt with the fermentation; and freely give out their contents. But there are ſome ſmall kinds with tough ſkins, which, if employed for this purpoſe, ſhould be bruiſed: or they will reſiſt the penetration of the water. Theſe kinds are not, however, ſo good for the purpoſe of making wine as the larger; or, at leaſt, if they be choſen for any particular flavour, they may give the wine, there ſhould be only a certain proportion mixt, added to ſome of the other kinds: and, in this caſe, they ſhould be firſt bruiſed.

"The practice of a double fermentation, as here directed, firſt of the raiſins themſelves, and afterwards of the ſugar, is not the common method: and very good wine may be made, by fermenting both at the ſame time. But this method is, nevertheleſs, preferable; for it ſometimes happens, from ſome unknown circumſtances in the fermentation, when ſuch method is not practiſed, that the wine will turn out cloudy, and not admit of being fined, by any means at preſent underſtood: which accident is prevented by this double fermentation remaining, as the ſecond perfectly works all the remaining half fermented part of the pulp. Moreover, in conſequence of this more perfect fermentation, the wine is lighter, and becomes wholeſome and perfect with leſs age: the glutinous matter of the raiſins being intirely reſolved.

"Of this wine, by adding the proper flavour, may be formed, imitations of all the natural wines, of a very ſtrong body: and, by abating the proportion of raiſins, ſugar, or both, other ſmaller kinds, may, by the ſame means, be produced.

"If this wine be perfectly fermented, and kept a long time, ſo that no ſweetneſs remain, it will reſemble Madeira: and has very frequently paſſed for it.

"An imitation of Frontiniac may be made, by the wine, in which the proportion of ſugar, or of malt-ſpirits, to the raiſins, is large; and the whole body weaker. The muſcadel flavour of Frontiniac, being exactly to be imitated, by an infuſion of the flowers of meadow-ſweet, in ſome of the wine: and added in that proportion, which may be found ſufficient to raiſe the due degree of the flavour. In the making this artificial Frontiniac, the fermentation ſhould be ſtopt, by cloſing the caſk, and adding the ſpirit, while a conſiderable ſweetneſs yet remains: and the wine may be drunk after it has been a ſhort time in bottles.

"Cyprus wine may be imitated, alſo, by the ſame means: the infuſion of the meadow-ſweet being added to the wine prepared in the beſt manner above directed. But, in this caſe, three or four pounds more of ſugar, than the quantity given in the recipe, ſhould be uſed; and the fermentation ſtopt, while a conſiderable degree of ſweetneſs remains. This kind will be the better for age: and, if properly managed, can never be diſtinguiſhed, even by actual compariſon, from the true Cyprus: as I can aſſert from the fact itſelf.

"The imitation of mountain is to be made, by preſerving a ſmall degree of ſweetneſs, giving the nut-like flavour, and keeping the beſt kind of the above wine to a due age. This nut-like flavour may be obtained, by the infuſion of the Florentine orris-root, powdered with a very ſmall proportion of orange and lemon-peel: and the wine may be rendered more dry or ſweet, by continuing the fermentation a greater or leſs time; and adding a correſpondent proportion of clean malt-ſpirits, when the fermentation is ſtopt ſooner. The adding ſome of the ſtony ſeeds of the raiſins well bruiſed, alſo, gives the nut-like flavour: and the putting in a part of the ſtalks of the raiſins, gives a ſharpneſs, found in general in this kind of wine.

"The racy taſte of canary, now commonly called ſack, may be counterfeited by the addition of a proper quantity of the juice of white currant-berries to the wine, made with a large proportion of ſugar to the raiſins; and left very ſweet in the fermentation. But it is ſaid, that a ſpirit, diſtilled from the leaves of clary and clean malt-ſpirits, and put to the wine, will give to it ſuch a ſtrong reſemblance of ſack, as renders it abſolutely undiſtinguiſhable from that wine.

"It is ſaid, alſo, that the juice of the bramble-berries, added to the mixture of the wine, before the fermentation, gives both the exact colour, and flavour of claret. But, in this caſe, the quantity of raiſins ſhould be conſiderably diminiſhed, and that of the ſugar increaſed, though not to the full proportion: as the fermentation muſt be continued till all ſweetneſs be deſtroyed; and this wine is not intended to have ſo great a body as the others.

"It is better, therefore, for this imitation of claret, to work it only of moderate ſtrength; and to add ſome proportion of diſtilled ſpirit: it will be perfect at the end of two years. This, and the imitation of ſack by the ſpirit of clary, I have never ſeen tried: but have them on very good authority. I ſhould be apt to believe, a ſmall proportion of red-argol, or tartar, diſſolved in ſome of the wine, and added together with the ſpirit, when the bung is cloſed up, would aſſiſt the imitation very materially.

"Any

"Any intelligent perſon may eaſily collect, from theſe inſtructions, ſufficient lights to qualify them to make better or cheaper kinds of wine, according to their inclination. But whatever kind is made, at leaſt a year ſhould be given to it: and, in moſt caſes, a longer time. For nothing has ſo much contributed to the diſcrediting, and excluding the uſe of domeſtic wines, as the drinking them too new: eſpecially after an injudicious, and undue management of the fermentation; by which means they have been made to appear flatulent, aceſcent, and foul. But the very oppoſite of theſe qualities will be found in them, when properly treated and kept."

To WINNOW, to clear corn from the chaff, &c. *See the article* THRASHING.

WITHERS, the part of a horſe where the ſhoulder bones join at the bottom of the neck and mane.

All pinches of the ſaddle on the withers, ſhould be treated with repellers; for this purpoſe bathe the tumor well with hot vinegar three or four times a day: if that does not ſucceed alone, an ounce of oil of vitriol may be put to a quart of vinegar, or half an ounce of white vitriol diſſolved in a little water, and added to the ſame quantity. Theſe are generally very effectual repellers for this purpoſe in horſes, and will frequently prevent impoſthumation: when the ſwelling is attended with heat, ſmarting, and little hot watery pimples, the following mixture will then be more proper to bathe with.

Take two ounces of crude ſal ammoniac, boiled in a quart of lime water, where that cannot be had, a handful of pearl or wood-aſhes may be boiled in common water; pour off the decoction when ſettled, and mix with it half a pint of ſpirit of wine: anoint the part afterwards with linſeed oil, or elder ointment, to ſoften and ſmooth the ſkin.

But when theſe ſwellings are critical, the conſequence of a fever ſettled on this part, you muſt avoid the repelling method, and aſſiſt in bringing the ſwelling to matter, by means of ſuppurating poultices: experienced farriers adviſe never to open theſe tumors till they break of themſelves; for if they are opened before they are ripe, the whole ſore will be ſpongy, and diſcharge a bloody ichor, which ſoon degenerates into a ſordid ulcer. But take care to inlarge the openings and pare away the lips, that your dreſſings may be applied eaſily; and avoid the ligament which runs along the neck to the withers: if a gathering forms on the oppoſite ſide, open it in the ſame manner, but take care they incline downwards, for the ſake of dedepending orifices, and letting the matter flow off eaſily, and if the bones ſhould be found foul, they muſt be dreſſed with tincture of myrrh till they ſcale off: if the fungus is very troubleſome, and the diſcharge, oily, yellow and viſcid; pledgits ſoaked in the following, made hot, have been found very effectual, bathing the ſwelling round with ſpirit of wine and vinegar.

Take half an ounce of blue vitriol, diſſolved in a pint of water; oil of turpentine, and rectified ſpirit of wine, of each four ounces; white wine vinegar, ſix ounces; oil of vitriol and Ægyptiacum, of each two ounces.

Theſe ſharp liquid applications are often found more efficacious dreſſings than ointments with precipitate, or verdigreaſe, or indeed any other digeſtives; as they inſinuate themſelves more readily into the interſtices of the funge, or little quag-holes, ſo commonly obſerved in theſe kind of ulcers; and, at the ſame time, level and deſtroy the riſing, and exuberant papillæ; whereby the ulcer grows more ſmooth and dry, ſoon heals up, and cicatriſes.

When the cavities are truly fiſtulous, the calloſities muſt be cut out, where it can be done, with a knife; and the remainder deſtroyed by corroſives; viz. precipitate, burnt allum, and white vitriol. *Bartlet's Farriery, p.* 273.

WITH-WIND, *See the article* BIND-WEED.

WOAD, the Engliſh name of a plant, called by botaniſts *Iſatis ſativa, vel latifolia.*

This plant puts forth ſtems about three feet high, and of the thickneſs of a man's finger: theſe divide at their top into ſeveral branches loaded with many leaves irregularly placed; and theſe leaves, which reſemble pretty much thoſe of dog's-tongue, are ſleek, and of a bluiſh green colour. The branches bear alſo great numbers of flowers compoſed of four yellow petals diſpoſed croſs-wiſe: the pointal becomes a capſule flattened on the edge, and each capſule contains two oblong ſeeds; the root is large, woody, and penetrates deep into the ground. This plant delights in a warm climate, ſuch as Italy aud the ſouthern parts of France: tho' it has likewiſe been cultivated in Normandy, and is ſaid to ſucceed in Germany; as experience has ſhewn that it does alſo in this country.

A light, black, kindly, and rich ſoil, or a meadow newly broken up, is choſen for the cultivation of woad; but it muſt not by any means be ſown on ſtoney or ſhallow land. It thrives well in plains, but ſtill better on the ſouth ſide of a hill: the eſſential point is, that the ſoil be good, and that it have the above-mentioned qualities.

Though the land which is intended for woad be never ſo good, it muſt be dunged a year before it is ſown with this plant, and be made firſt to bear a crop of wheat, or of onions, &c. After theſe are taken off, three deep ſtirrings ſhould be given with the plough, or, which is much better, with the ſpade: the firſt ſtirring ſhould be in November, and the other two in February, March, or April. If the land which is intended for woad lies flat, and has not ſlope enough to carry off the wet, channels muſt be cut of a greater or leſs ſize, according as the ground is more or leſs diſpoſed to retain the water.

In warm climates, woad is ſown ſo early as the beginning of April, unleſs the weather chances then to be too cold, in which caſe this ſowing is deferred till the beginning of May: but for countries like ours, where the ſpring is attended with froſts, particularly in the night, Mr. Miller is cerrtainly right in adviſing to lay the land up in narrow high ridges juſt before winter, that the froſt may mellow it; to croſs-plow it in the ſpring, laying it again in narrow ridges, and between this time and the enſuing month of June to harrow it well twice, at different intervals, in order to root up whatever weeds may have appeared: then, in June, to give the ground a third plowing as deep as the plough will go, making the furrows narrow; after this, to harrow it again when any new weeds are come up; and finally, towards the end of July, or the beginning of Auguſt, to plow it for the laſt time, laying it as ſmooth as poſſible. A good harrowing after this will fit it completely to receive the ſeeds, which, if rain falls ſoon after their being ſown, or if they are ſteeped in water during the

night before the ſowing, as Mr. Miller adviſes, will appear in a fortnight, if the ſeaſon be favourable. They ſhould be but lightly covered, and ſhould be ſowed ſo thin as that the plants may ſtand ſix inches aſunder. Some ſtrew pigeon's dung on the land juſt after having ſown it with woad, and the plants become much the finer for this manure.

It is a common cuſtom to ſow woad in broad-caſt: but all plants which require being hoed ſhould certainly be ſowed in rows, becauſe this method greatly leſſens the labour and time of hoeing; and beſides, it is much eaſier, in this caſe, to give each plant its due diſtance.

When the woad is grown large enough to be diſtinguiſhed, it ſhould be carefully cleared of all weeds, for theſe would hurt it greatly; and at the ſame time the plants ſhould be thinned wherever they ſtand too cloſe: without this precaution, the woad would produce but very few leaves, and would remain extremely ſtinted in its growth.

The intervals between the plants ſhould be ſtirred whenever the ſeaſon requires it; and in the doing of this, by which the weeds thereby rooted out will ſoon be deſtroyed in dry weather, care ſhould be taken to lay a little earth up around the ſtems of the woad. M. Du Hamel, whoſe account we have here reſumed, ſays he has been aſſured, that, in countries where there is a convenieny of water, the woad-grounds are flooded; but to reap any benefit from this practice, the water ſhould be in ſufficient plenty for the huſbandman to be able to repeat the flooding frequently; for otherwiſe the heat of the ſun, after having exhaled the water too ſoon, would harden the ſurface of the earth, and thereby greatly injure the plants.

Woad generally affords two crops in the ſame year, and ſometimes, when the ſeaſon has been favourable, it has yielded even four. The two firſt are the beſt, and theſe are commonly mixed rogether in the manufacturing of this plant: but the after-crops are always kept ſeparate; for if theſe are mixed with the other, the whole will be ſpoiled. The two firſt crops will ſell for from twenty-five to thirty pounds a ton; but the latter will not bring more than ſeven or eight pounds, and ſometimes not ſo much. An acre of land well huſbanded will produce a ton of woad, and in good ſeaſons near a ton and a half. The firſt crop is gathered towards the end of Auguſt, and the laſt at the end of October, or in the beginning of November: but this laſt crop muſt be got in before the firſt froſts come on; for the leaves that might be gathered afterwards would not be worth any thing. When the plant is ripe, which is known by its firſt leaves begiming to dry, all the leaves are cut off by a man who graſps the plant by handfuls, and they are then laid in a heap to wither. Whilſt they are in this ſituation, they muſt be ſheltered from the ſun and rain, and they muſt be frequently turned, in order that they may heat equally: they are then carried to a mill ſomewhat like that which is uſed for preſſing the oil out of linſeed, and are there ground till they are reduced into a paſte, which is afterwards formed into cakes of about a pound weight, and theſe are laid to dry in a covered place, where neither the ſun nor rain can come to them. This paſte is dried thus for about a fortnight, that is to ſay, till it has acquired conſiſtence enough to be formed into ſmall roundiſh lumps, by means of little wooden moulds into which it is put for that purpoſe. As faſt as theſe lumps are taken out of the moulds, they are laid upon wicker hurdles looſely woven, ſo as not to touch one another, and in ſuch manner that the air may come at every part of them, as is practiſed in the drying of ſtarch. Theſe lumps become very hard, and in this condition it is that they are ſold. When they are to be uſed, they muſt be ſteeped a long while in water before they can be broken.

The woad thus prepared yields an excellent blue dye, very laſting, and with which all the degrees of this colour may be made. It is not long ſince this plant was preferred to indigo: afterwards through a kind of toleration, the dyers were allowed to put a ſmall quantity of indigo into their vats of woad; but now that the making and manner of uſing indigo have been greatly improved, it is looked upon as a matter of indifference whether that or woad be uſed for dying blue.

At the laſt cutting of the woad, and with that cutting, the crown of the root is taken off; whereas only the leaves were gathered in the preceding cuttings. When it is intended to ſave the ſeed of woad, a ſmall portion of the plantation ſhould be allotted for this purpoſe at the laſt cutting, and then a part only of the leaves there ſhould be taken from the plants: but it is proper to retrench ſome of them, becauſe experience has ſhewn that the plants on which all their leaves are left run to ſeed too ſoon, and that their ſeeds have in this caſe often been deſtroyed by the cold of the enſuing ſpring. Thus woad, being a biennial plant, ſhould not be ſuffered to ſeed before the month of Auguſt in the ſecond year after it has been ſown; and therefore ſome of its leaves ſhould be cut off in October, to prevent its being too forward.

Beſides cold, weeds, and drought, which are very pernicious to woad, locuſts will ſometimes devour a whole field of it in an evening. When theſe enemies are obſerved, all the leaves ſhould be immediately cut off, that the plants may put forth new ones.

The ſame field ſhould not be made to bear a ſecond crop of woad immediately after the firſt; for this plant is a great impoveriſher of the ground: but after it has been taken off, wheat may be ſown the firſt year, millet the ſecond, and in the third it may be laid down again to woad, if it has been well manured.

WOLVES TEETH, a name given to thoſe teeth, which grow in ſuch a manner, that their points prick, or wound either the tongue, or gums, in eating. Old horſes are moſt liable to this infirmity, and whoſe upper overſhoot the under teeth in a great degree.

To remedy this evil, you may either chop off the ſuperfluous parts of the teeth with a chizzel and mallet, or file them down, which is the better way, till you have ſufficiently waſted them.

WOOD, a large and thick plantation of trees.

The two moſt ſubſtantial timbers of this country are the oak and cheſnut; though the latter has been of late years almoſt entirely deſtroyed in England, ſo that there are ſcarce any remains of trees of ſize in the woods at preſent; but there can be no doubt of this tree having been one of the moſt common trees in this country, as may be proved by the old buildings in many parts of England, in which the greateſt part of the timber is cheſnut. Next to theſe, the elm is eſteemed as a profitable timber; but of theſe there are few cultivated in woods, eſpecially in the ſouth part of England, where they chiefly grow in hedge-rows, or plantations, near houſes; but in the north-weſt part of England, there are numbers of very large trees of the witch-elm growing in parks, and ſome in woods,

woods, as if that tree was a native of this country, which has been much doubted; though as this tree propagates itſelf by ſeeds, it may be deemed an indigenous plant in England.

The beech is another tree common in the woods, eſpecially upon the chalky hills of Buckinghamſhire, Kent, Suſſex, and Hampſhire, where there are ſome very large woods entirely of this ſort; ſome of which have been of long ſtanding, as appears by the age of the trees; but whether this tree is a native of this country, has been a point often diſputed.

The aſh is a very profitable tree, and of quick growth; ſo that in leſs than an age, the trees will arrive to a large ſize from the ſeeds, therefore a perſon may hope to reap the profits of his labour, who ſows the ſeeds; but this is not a beautiful tree to ſtand near a habitation, being late in the ſpring in putting out its leaves, and the firſt that ſheds them in autumn; nor is it a friendly tree to whatever grows near it, the roots drawing away all the nouriſhment of the ground, whereby the trees or plants which grow near are deprived of it; ſo that where the aſh grows in hedge-rows, the hedges in a few years are entirely deſtroyed; and if they are in paſture-grounds, and the cows browze on them, the butter made with their milk will be bad; for which reaſon the aſh ſhould be ſown ſeparate in lands which are incloſed, where cattle are not permitted to come, and at a diſtance from the habitation.

Upon ſandy or rocky ſoils, the Scotch pine will thrive exceedingly, and turn to great advantage to the planter, provided the plants are planted young, and treated in a proper manner. There are alſo ſeveral aquatic trees, which are very profitable to thoſe who have low marſhy lands, where the harder kinds of timber will not thrive; theſe are the poplars of ſeveral ſorts, the willow, alder, &c.

Where there are young woods, great care muſt be taken of the fences; for if cattle ſhould get in among the trees, they will, in a ſhort time, do infinite damage to them, by browzing on their branches, or barking the trees; and during the firſt ten years of their growth, they ſhould be ſecured from hares and rabbits, otherwiſe, in ſevere froſt, when the ground is covered with ſnow, whereby they are deprived of other food, they will get into the woods, and eat off the bark from the young trees, and gnaw all the branches w thin their reach; ſo that in a few days, where there are plenty of theſe animals, there may be ſuch deſtruction made among the young trees, as cannot be retrieved, but by cutting them down to the ground, which will be a loſs of ſeveral years; therefore thoſe perſons who have the care of young woods ſhould be very diligent in froſty weather in looking over the trees and ſtopping holes in the fences, to keep out all vermin.

Another care to be taken of young woods, is the thinning the trees from time to time, as they increaſe in their growth; but in doing of this, there muſt be great caution uſed, for it ſhould be gradually performed, ſo as not to open the trees too much, to let the cold air among them, which will greatly retard their growth; nor ſhould the trees be left ſo cloſe, as to draw each other up like Maypoles, but rather obſerve a medium in this work, cutting down a few each year, according as there may be neceſſity for it, being careful not to permit thoſe to ſtand, which may ſpoil the growth of the neighbouring trees, always obſerving to leave thoſe trees which are the moſt promiſing.

The young trees in theſe woods ſhould not be lopped or pruned, for the more they are cut the leſs they will increaſe in bulk; every branch which is cut off will rob the tree of its nouriſhment, in proportion to the ſize of the branch; therefore the hatchet ſhould not be ſuffered to come into young woods, unleſs in the hands of ſkilful perſons.

Where perſons have more regard to the future welfare of the timber than their immediate profit, the underwood ſhould be grubbed up as the trees advance, that the roots may have the whole benefit of the ſoil, and their ſtems enjoy the free air, without which their ſtems are generally covered with moſs, and their growth greatly ſtinted; as may be obſerved in all ſuch woods where there is any quantity of underwood remaining, in which places it is rarely found that the trees do ever grow to a large ſize; therefore when large timber is deſired, the trees muſt have room to extend their roots and branches, without which it cannot be expected: but from a covetous temper, many people let their underwood remain as long as it will live; for as the timber increaſes, the underwood will be gradually decaying by the ſhade and drip of the large trees, ſo that by this method the timber ſuffers more in a few years than the value of the underwood; therefore by endeavouring to have both, neither of them can be ſo good as where they are ſeparately preſerved.

If perſons who have eſtates would be careful to nurſe up trees in their hedge rows, it would in time become a fortune to their ſucceſſors; as hereby the timber growing in the hedges may be worth more than the freehold of the eſtate, which has often been the caſe with eſtates from which their poſſeſſors have cut down timber for fortunes for their younger children; the frequency of this ſhould encourage perſons to be a little more attentive to the growth and preſervation of young woods, ſince the expence and trouble is not great, and the future profit very certain; beſides, the pleaſure of ſeeing trees of a man's own ſowing make yearly advances, muſt be very great to thoſe who have any reliſh for country amuſements.

There are ſeveral perſons who plant copſes for cutting every ten or twelve years, according to their growth. Theſe are uſually planted in autumn, either with ſtools or young plants, which are drawn out of the woods; the latter ſhould always be preferred to the former. Theſe copſes are commonly planted with ſeveral ſorts of trees, as oak, beech, cheſnut, aſh, birch, willows, &c. But the aſh and cheſnut are the moſt profitable, where they grow kindly, becauſe the poles of aſh are very valuable; theſe alſo are good for hoops, ſo that there is no danger of having ſale for theſe copſe woods when they are fit for cutting; but where the copſes are intended to remain, there ſhould be no ſtandard trees left for timber, becauſe as the heads of the trees ſpread, and over-top the underwood, it will cauſe that to decay, and where the ſtandards are left upon the ſtumps of the copſe wood they will never grow to a large ſize, nor will the timber be ſo valuable as that produced immediately from a young root; therefore whoever will make the experiment, will be convinced that it is more for the advantage of both to keep them in diſtinct woods.

But where perſons plant copſes upon land free from trees, it will be the better method to ſow the ſeeds, eſpecially if cheſnut, oak, or beech, are the trees intended; for although it is a prevailing opinion with the generality of perſons, that by planting they ſave time, yet I am ſure of the contrary; for if the ſeedling plants are kept clear from weeds, they will, in eight or ten years, out-grow thoſe which are planted; and theſe unremoved copſes will

will continue much longer in vigour than the other; ſo that for either timber or copſe wood, the beſt method is to prepare the ground well, and ſecure the fences and ſow the ſeeds, which is ſo far from loſing, that in twenty years it will be found to gain time, which is what every planter wiſhes to do.

The uſual time of felling timber is from November to February, at which time the ſap in the trees is hardened; for when the ſap is flowing in the trees, if they are cut down the worm will take the timber, and cauſe it to decay very ſoon; therefore if the durableneſs of the timber is conſidered, the trees ſhould always be cut in the winter months; but as the bark of the oak is ſo very valuable for tanning leather, there has been a law paſſed to oblige perſons to cut theſe trees during the ſpring-ſeaſon, when the bark will readily peel off, by which the timber is rendered unfit for building either ſhips or houſes, as it will be very ſubject to caſt, rift, or twine, and the worm will ſoon take it; therefore it will be more for the public benefit, if a law was enacted to oblige every perſon to ſtrip off the bark of ſuch trees, as are deſigned to be cut down in the ſpring, when the bark will run, leaving the trees with their branches ſtanding till the following winter, which will be found to anſwer both purpoſes well. *Miller's Gard. Dict.*

WOOD-COCK *Soil*, ground whoſe ſoil under the turf is of the colour of a wood-cock, and is not good.

WOOD-LAND, ground covered with woods. It is alſo a term uſed, by the farmers of many counties of England, for a ſort of ſoil, from its conſtant humidity and dark colour, reſembling the ſoil in woods, which, of whatever nature it originally is, will always be made to appear thus from the continual dropping of trees, and the want of a free air and ſun, together with the fall of leaves, deſtroyed and waſhed to pieces by the wet.

This ſoil in the open countries has a conſiderable quantity of clay in it, and holds the water a long time that once falls upon it: in wet weather it ſticks firmly to the ploughſhare; and, in dry, is very apt to crack. In uncultivated places it uſually produces ruſhes and ruſh-graſs. A moiſt and dripping year is extremely detrimental to this ſort of land.

WOODY, abounding with wood.

WOOL, the covering of ſheep. Each fleece conſiſts of wool of ſeveral qualities and degrees of fineneſs, which the dealers therein take care to ſeparate.

The Engliſh and French uſually ſeparate each fleece into three principal ſorts, viz. 1. Mother-wool, which is that of the back and neck. 2. The wool of the tails and legs. 3. That of the breaſt and under the belly. The wool moſt eſteemed is the Engliſh, chiefly that about Loeminſter, Coltſwold, and the Iſle of White; the Spaniſh, principally that about Vegovia; and the French, about Berry.

An account of three experiments made to diſcover whether wool, laid up in the fleece, alters in its weight.

It has been a matter of ſome doubt amongſt graſiers, farmers, and dealers in wool, whether or not wool, after it is ſhorn and laid up in the fleece, alters in its weight. The following experiments were made to decide this queſtion.

EXPERIMENT I.

This wool was ſhorn dry, and laid up in a two-pair of ſtairs room, on a boarded floor.

	Weight lb.	oz.
1746, Aug. 10	76	6
Sept. 7	76	8
Oct. 14	77	11
Nov. 18	78	0
1747, Jan. 26	80	0
Feb. 20	80	4
Mar. 23	79	8
Apr. 18	77	13
June 24	76	8
July 28	76	8
Sept. 16	75	15
Nov. 2	78	1
Dec. 8	78	14
1748, Feb. 15	79	1

The weight was increaſed from Auguſt 10, 1746, (when it was firſt laid up) to February 20, 1747, in the proportion as 100 to 105.

EXPERIMENT II.

This wool was ſhorn dry, and laid in a lower room, with a brick floor one foot above the floor.

	Weight lb.	oz.
1749, Oct. 15	100	4
Nov. 18	101	2
1747, Jan. 26	102	8
Feb. 20	102	11
Mar. 23	102	9

The weight increaſed from October 15, 1746, to February 20, 1747, as 100 to 102.½

N. B. It is ſomething difficult to account for this parcel of wool not encreaſing more in its weight, as it lay ſo near the ground floor; but very probably the air had been very damp and raw from the time it was ſhorn till the 15th of October, 1746, when it was firſt weighed, ſo that the wool had then very likely gained weight conſiderably.

EXPERIMENT III.

This wool was ſhorn dry, and laid up in a two-pair-of-ſtairs room, with a boarded floor.

	Weight lb.	oz.
1756, Aug. 30	36	9
Nov. 19	37	2
Feb. 19	37	12
Mar. 24	37	6
April 1	37	4
Ditto 21	36	14
May 2	36	13
June 1	36	8½
Ditto 13	36	4
July 8	36	1½
Ditto 27	35	12
Sept. 30	36	4
1758, Jan. 25	37	11½

The weight of this wool encreaſed from the time it was laid up, Auguſt 30, 1756, to February 19, 1757, as 100 to 103¼.

Both wool, and woollen rags, make an excellent manure.

WORMS are very prejudicial to corn fields, eating up the roots of the young corn, and deſtroying great quantities of the crop. Sea-ſalt is the beſt of all things for deſtroying them. Sea-water is proper to ſprinkle on the land, where it can be had; where the ſalt ſprings are, their water do; and where neither are at hand, a little common or bay-ſalt does as well. Soot will deſtroy them in ſome lands, but is not to be depended upon, for it does not always ſucceed. Some farmers ſtrew on their lands a mixture of chalk and lime; and others truſt wholly to their winter-fallowing to do it, if this is done in a wet ſeaſon, when they come up to the ſurface of the ground, and ſome nails with ſharp heads be driven into the bottom of the plough. If they are troubleſome in gardens, the refuſe brine of ſalted meat will ſerve the purpoſe,

poſe, or ſome walnut leaves ſteeped in a ciſtern of water for a fortnight or three weeks, will give it ſuch a bitterneſs that it will be a certain poiſon to them. A decoction of wood-aſhes, ſprinkled on the ground, will anſwer the ſame purpoſe; and any particular plant may be ſecured both from worms and ſnails by ſtrewing a mixture of lime and aſhes about its roots. It is a general caution among the farmers to ſow their corn as ſhallow as they can, where the field is very ſubject to worms.

WORMS, a well known ſpecies of inſects, very troubleſome to horſes.

Authors have deſcribed three different ſorts of worms that affect horſes, *viz.* bots, which young horſes are often troubled with in the ſpring: the rotundi, or thoſe reſembling earth-worms; and the aſcarides, or thoſe about the ſize of the largeſt ſewing needle, with flat heads.

For the method of curing the bots, *ſee the article* BOTS.

As the ſource of worms in general proceeds from a vitiated appetite and a weak digeſtion, recourſe muſt firſt be had to mercurials, and afterwards to ſuch things as are proper to ſtrengthen the ſtomach, promote digeſtion, and by deſtroying the ſuppoſed ova, prevent the regeneration of theſe animals. Thus, two drams of calomel may be given with half an ounce of diapente, and mixed up with conſerve of wormwood over night; and the next morning the above purge: theſe may be repeated in ſix or eight days. Or the following mercurial purge may be given, which will be leſs troubleſome, and no leſs efficacious.

Take crude quickſilver, two drams; Venice turpentine, half an ounce; rub the quickſilver till no gliſtening appears; then add an ounce of aloes, a dram of grated ginger, thirty drops of oil of ſavin, and a ſufficient quantity of ſyrup of buckthorn to make a ball.

One of theſe balls may be given every ſix days, with the uſual precautions in regard to mercurial phyſick; and theſe powders intermediately.

Take powdered tin and Æthiops mineral, of each half an ounce: give every night in a maſh, or his corn.

The various preparations of antimony and mercury muſt be given ſeveral weeks together, in order to get entire riddance of theſe vermin. The Æthiops mineral may be given to the quantity of half an ounce a day; the mercurius alkaliſatus to two drams a day, incorporated with a bit of cordial ball. The cinnabar powders, as directed in the farcy, are no leſs effectual: and when worms are bred from high feeding, or unwholſome food; rue, garlick, tanſy, ſavin, box, and many other ſimples, may be given ſucceſsfully; being for that purpoſe mixed with their food; as alſo, cut tobacco, from half an ounce to an ounce a day.

As the generation of worms perhaps principally proceeds from a weak ſtomach, and bad digeſtion, if the horſe be of a tender conſtitution, and a bad feeder, the following bitter drink ſhould be given to ſtrengthen his ſtomach, and mend his digeſtion; which will prevent the formation of theſe animals, interpoſing now and then a gentle ſtomach purge, prepared with an ounce and half of hiera picra made up into a ball, with ſyrup of buckthorn.

Take gentian root, zedoary and galangals of each two ounces; chamomile flowers, and tops of centaury, of each two handfuls; Jeſuits bark powdered, two ounces; filings of iron half a pound; juniper berries four ounces: infuſe in three gallons of ale for a week, ſhaking the veſſel now and then: and give a pint of this night and morning.

To anſwer this purpoſe alſo, an ounce of filings of ſteel finely powdered, has been ſucceſsfully given every day for a fortnight, or longer, in the horſe's corn. *Bartlet's Farriery, pag.* 150.

WOUND, a hurt given by violence.

In all freſh wounds made by cutting inſtruments, there is nothing more required than bringing the lips of the wound into contact by ſuture or bandage, provided the part will allow of it; for on wounds of the hips, or other prominent parts, and acroſs ſome of the large muſcles, the ſtitches are apt to burſt on the horſe's lying down and riſing up in the ſtall; in ſuch caſes the lips ſhould not be brought cloſe together; one ſtitch is ſufficient for a wound two inches long; but in large wounds they be at an inch or more diſtance; and if the wound is deep in the muſcles, care ſhould be taken to paſs the needles proportionably deep, otherwiſe the wound will not unite properly from the bottom.

Should the wound bleed much from an artery divided, the firſt ſtep ſhould be to ſecure it, by paſſing a crooked needle underneath, and tying it up with a waxed thread: if the artery cannot be got at this way, apply a button of lint or tow to the mouth of the bleeding veſſel, dipped in a ſtrong ſolution of blue vitriol, ſtyptic water, oil of vitriol, or hot oil of turpentine, powdered vitriol, or colcothar, &c. and remember always to apply it cloſe to the mouth of the bleeding veſſels, and take care that it is kept there by proper compreſs and bandage, till an eſchar is formed; otherwiſe it will elude your expectations, and frequently alarm you with freſh bleedings.

I purpoſely avoid ſetting down any famous receipts for freſh wounds, whether ointments, or Fryar's balſams, being well aſſured, that in a healthy ſound conſtitution, nature furniſhes the beſt balſam, and performs herſelf the cure, which is ſo often attributed to the medicine; when it is otherwiſe, and the blood is deprived of its balſamic ſtate, as will appear from the aſpect of the wound, and its manner of healing, it muſt be rectified by proper internal medicines, before a good foundation for healing can be laid by any external applications whatever.

The lips of the wound then being brought together by the needle or bandage, it needs only to be covered with rags dipped in brandy, or a pledgit of tow ſpread with the wound ointment, and the wounded part kept as much as poſſible from motion.

Remember to dreſs all wounds of the joints, tendons, and membranous parts, with terebinthinate medicines: to which may be added honey and tincture of myrrh; and avoid all greaſy applications whatever; fomentations and poultices are alſo generally here of great uſe; the former thin and attenuate the impacted fluids, greatly promote a free perſpiration in the limb, and facilitate the unloading the ſurcharge on the veſſels, by quickening the motion of the

the fluids; while the latter, by relaxing the veſſels, abate their tenſion, and relieve the obſtruction, by promoting digeſtion.

Punctured wounds from thorns, or any other accidents, ſhould be treated in the ſame manner; applying the beer, or bread and milk poultice over the dreſſing, till ſome ſigns of digeſtion appear; and fomenting the part well every day. This method is alſo very ſucceſsfully uſed to thoſe ſwellings, which often ariſe on the neck from bleeding, the ſores being ſprinkled with precipitate, and burnt allum powdered, to fetch out the core, or fungus, which choaks up the orifice. The uſual method is to introduce a piece of vitriol, or ſublimate, which often brings on a plentiful diſcharge, fetches out the core, and makes a cure; but it is often with the loſs of the vein, and it ſometimes leaves a large ſwelling and impoſthumation.

In gun-ſhot wounds, when the ball has not penetrated too deep, it ſhould be extracted, if it can be fetched away without diſturbance, together with any extraneous bodies that might paſs in with it; the wound ſhould be dreſſed with the old digeſtive of Venice or common turpentine, divided with the yolks of eggs, to which may be added ſome honey and tincture of myrrh. The entrance of theſe wounds frequently requires to be enlarged, and a depending orifice ſhould always be procured if poſſible; and if the wound ſhould not digeſt kindly, apply the beer poultice, and foment with the diſcutient fomentation.

In ſcalds, or burns from gunpowder, or any other cauſe, when the ſkin remains intire, bathe the part well, and keep it ſoaked with rags dipped in ſpirit of wine camphorated: ſalt bound thick on the part has been found very effectual for this purpoſe: and indeed all ſaline and ſpirituous applications excel others, while the ſkin is yet unbroke; but when the ſkin is ſeparated, anoint the part, and keep it conſtantly ſupple with linſeed or ſallad oil, and a plaiſter ſpread with bees-wax and oil; if the ſkin is ſo ſcorched, that ſloughs muſt be digeſted out, dreſs with the wound ointment and oil of turpentine, and finiſh the cure with any drying oinment. Should the horſe be feveriſh from the pain, bleed him, give cooling glyſters, and treat him as we have directed in ſimple fevers.

The fire ſuppoſed to be left in the part after injuries of this kind, is nothing more than the inflammation, which is the natural effect of ſuch cauſes; ſo that the whimſical notions and conceits concerning fire remaining in the burnt part, is extremely abſurd.

Wounds in the feet from nails, gravel, &c.

Accidents of this ſort are very common, and ſometimes for want of early care, prove of bad conſequence: for the parts being naturally tender, are very ſuſceptible of inflammation; and when matter is once formed, if a free diſcharge is not procured, the bone, which is ſpongy, ſoon becomes affected, and the whole foot is then in danger.

When any extraneous bodies, ſuch as nails, ſtubs, thorns, &c. have paſſed into the horſe's foot, you ſhould endeavour to get them out as ſoon as poſſible; and after waſhing the part with oil of turpentine, dreſs the hole with lint dipped in the ſame, melted down with a little tar; the foot may be ſtopped up with bran and hogs-lard heated together, or put into the turnep, or any ſoft poultice: this method is generally ſucceſsful, when the nail, &c. is intirely removed; but if any piece, or particle, ſhould remain behind, which may be ſuſpected by the degree of pain, and diſcharge of matter; after paring away the ſole as thin as poſſible, introduce a bit of ſponge tent, in order to inlarge the hole, that it may be drawn out by a ſmall pair of forceps, or brought away by digeſtion: if this method ſhould not ſucceed, but the lameneſs continues, with a diſcharge of a thin, bloody, or ſtinking matter, you muſt no longer delay opening the wound with a drawing knife to the bottom, and then dreſs as above directed, or with the turpentine digeſtive, divided with the yolk of an egg, and a little tincture of myrrh afterwards with the precipitate medicine. *Bartlet's Farriery, p.* 246.

Y.

YARD-LAND, a quantity of land, in ſome counties fifteen acres, in ſome twenty, and in others, twenty-four, thirty and thirty-four acres.

YELLOWS, a diſeaſe incident to horſes and other cattle, and more properly called the jaundice. *See the article* JAUNDICE.

"Having, ſays a correſpondent of the editors of the Muſeum Ruſticum, noted the frequent fatal effects of the diſeaſe in cattle, called the yellows, I, ſome years ſince, reſolved to let no opportunity ſlip of being acquainted with this complaint, in order to aſſign its cauſe, inaſmuch as I apprehend it to be the forerunner of moſt chronical diſ-

caſes,

eaſes, to which great cattle are ſubject, as the murrain in the guts, ſcowering, aſthma, or wheezing, dropſy, and loſs of milk, &c.

" I have not hitherto been able to find any author who has treated of this complaint in a manner ſuitable to the conſequence thereof, ſo as to trace the ſymptoms in its ſeveral ſtages, in order to effect a cure; and, where this complaint has been quite neglected or ill cured, to point out the conſequence, by ſhewing how it may appear under the above-mentioned ſhapes, which, being miſtaken for originals when they are only conſequents, are rarely cured, through the firſt cauſe being unknown.

" This complaint, I apprehend, proceeds from a waſte of bile, that is, a preternatural running out of what is called gall; occaſioned by the rugæ, which are in the inner membrane of the neck of the bilious duct, becoming, by ſome accident, too weak to perform their office, ſo that the gall runs out of the bladder nearly as faſt as it runs in; by which means it forceth itſelf, or a conſiderable part at leaſt, into the porus bilarius, inſtead of being diſcharged by the ductus communis cholidochus into the inteſtines, and, by the means of the vena porta, mixes again with the blood, filling that with its ſharp pungent quality; which cauſeth that fluid to become of a ſizy nature, and, conſequently, to move ſlowly in the channels through which it paſſes; whence ariſes that ſluggiſh diſpoſition the beaſt in this complaint is ſubject to, and which is one of the firſt ſymptoms of the diſeaſe.

" And the liver, being deprived of the natural heat and weight thereof, is, together with the ſizineſs of the blood, rendered incapable of performing its office, ſo that the ſupply of bile is not equal to the expence; nor is the blood purified from it as it ought, but paſſes on together till it fixes in ſome part, and there (if not timely prevented) forms a tumor very prejudicial to the beaſt.

" Theſe tumors I have ſeen appear externally in the glands behind the ears, of the ſhoulders, and of the flank, in the dewlap, round the corner of the hoofs, and in the udder, or milk-bag; internally, in the form of water, in the veins of fat between the muſcular parts of the body, in the kidney fat, and even between the coats of the guts.

" When theſe tumors, which appear externally, come to ſuppuration, the beaſt commonly recovers, though frequently it be a long time firſt.

" The ſeaſons of the year in which cattle are moſt ſubject to this complaint, are for about the five firſt weeks after they are put out to graſs in the ſpring, during which time the ſeaſon is apt to be very warm at days and cold at nights; the graſs being alſo tender, and abounding with moiſture: and in like manner in autumn; at which time the days are alſo warm and nights cold; and the graſs, on account of autumnal rains, tender as in the ſpring, and more ſo, if the preceding ſummer was tolerably dry.

" The cattle at theſe ſeaſons being faint and very ſubject to perſpire much, by which the pores are greatly opened in the day, and ſudden cold coming on at night haſtily contracts them; and before the warmth of the next day becomes ſufficient to ſet the parts thus contracted at liberty, the matter, which ſhould have been diſcharged by perſpiration, returns into the blood in order to paſs off by urine, by which means a much greater quantity of bile is ſecreted than otherways would; which paſſing into its receptacle, the gall-bladder, cauſes it to extend to a preternatural ſize; thereby extending the paſſage by its preſſure, till the rugæ are ſcarcely to be ſeen: whereby the reſiſtance made by them is not equal to the preſſure of the bile, which, conſequently, forces its way haſtily into the blood, in the manner before obſerved, inſtead of paſſing off as excrement by the guts.

" The early ſymptoms attending this diſeaſe, are, a ſhaking of the beaſt in a morning, and more particularly the hinder parts, as the loins, thighs, and legs; hollowneſs of the eyes, and the hair ſtaring; a dry noſe, and if the cold taken be great, hanging of the ears, the ſwelling of the dewlap, of the glands of the ears, the ſhoulders, or the flanks, and of one or more quarters of the udder, or milk-bag in cows; with a ſudden decreaſe of milk, what remains becoming, after a few days, more yellow than uſual, and will, if boiled, curdle: the fore teeth are generally looſe, as tho' they would drop out.

" If theſe ſymptoms, eſpecially the firſt, remain unobſerved, as is often the caſe in barren cattle, and ſuch as range at large, it frequently happens that the diſorder ſettles in ſome inward part; as on the pericardium, which cauſes wheezing, and the haſk, and uncommon poverty; when in the guts and meſentery, (or ſweet-bread) cauſes the laſk and ſcowering; and when in the vein of fat, between the muſcles, cauſes the dropſy and uncommon weakneſs.

" In this laſt complaint, on opening a beaſt, the melt or ſpleen was very ſmall and thin, not half ſo large as in a healthy ſtate, as was alſo the liver; but otherways ſound and perfect, the gall-bladder of an uncommon thickneſs, and its contents very little.

" In opening a beaſt which was waſted, and ſubject to wheezing and the haſk, the pericardium was become hard, and inclined to calloſity towards the part which joined the heart: the heart unuſually large, but ſound: the lights very ſound, but ſmall: the melt or ſpleen thin and withered: and the liver dryiſh, with a few ſmall hard knots therein: the gall-bladder near as the former.

" I have obſerved theſe knobs in others, and generally found the gall-bladder, liver, and ſpleen, leſs or more affected; thoſe which had the laſk, and ſcowered, generally having their guts covered, the inſide with a large quantity of mucus reſembling frogs ſpawn: the fleſh of theſe is always of a yellow caſt.

" Having ſaid thus much of what I apprehend the cauſe, I will now preſcribe what I have very many times known uſed with good ſucceſs for a cure.

" Firſt, Suffer no blood to be taken away from the beaſt.

" Take a handful of rue tops, the like quantity of the greater celendine; ſhred them ſmall, and mix with them one ounce of turmerick root in powder (or inſtead thereof red ſanders); put theſe in three points of ſtale old ale or beer, and cauſe it juſt to boil up; when it is cold enough, give it the beaſt warm: there is no occaſion to keep the beaſt in before or after, unleſs the inclemency of weather oblige.

" Two of theſe drinks, at forty-eight hours diſtance, will perfect a cure, if the diſeaſe be not of long-ſtanding.

"Should a ſcowering be come on, then, after the firſt drink, give the following on the intermediate days.

Take two pounds of oak-bark, boil it in one gallon of water till one fourth be conſumed; ſtrain it; in this water boil two pounds of rice till it be ſoft; mix with it half a pound of the burnt cruſt of bread, taken from the underſide of the loaf; and to all this put two quarts of milk; let it boil for twenty minutes; divide it in two parts, and give one to the beaſt at a time warm." *Muſeum Ruſticum, vol.* II. *p.* 144.

YEOMAN, the firſt, or higheſt degree of the plebeians of England. The yeomen are properly freeholders, and who cultivate their own lands.

YEW-TREE, the name of a well known tree, common on cold ſoils in many parts of England. The timber of the yew-tree is much eſteemed for various uſes.

Theſe trees may be eaſily propagated by ſowing their berries in autumn, as ſoon as they are ripe, upon a bed of freſh undunged ſoil, covering them over about half an inch thick with the ſame earth.

In the ſpring the bed muſt be carefully cleared from weeds, and if the ſeaſon prove dry, it will be proper to refreſh the bed with water now and then, which will promote the growth of the ſeeds; many of which will come up the ſame ſpring, but others will remain in the ground until autumn or ſpring following; but when the ſeeds are preſerved above ground till ſpring before they are ſown, the plants never come up till the year after, ſo that by ſowing the ſeeds as ſoon as they are ripe, there is often a whole year ſaved.

Theſe plants, when they come up, ſhould be conſtantly cleared from weeds, which, if permitted to grow amongſt them, would cauſe their bottoms to be naked, and frequently deſtroy the plants when they continue long undiſturbed.

In this bed the plants may remain two years; after which, in autumn, there ſhould be a ſpot of freſh undunged ſoil prepared, into which they ſhould be removed the beginning of October, planting them in beds about four or five feet wide, in rows about a foot aſunder, and ſix inches diſtance from each other in the rows, obſerving to lay a little mulch upon the ſurface of the ground about their roots, as alſo to water them in dry weather until they have taken root; after which they will require no farther care, but to keep them clear from weeds in ſummer, and to train them according to the purpoſe for which they are deſigned.

In theſe beds they may remain two or three years, according as they have grown, when they ſhould again be removed into a nurſery, placing them in rows at three feet diſtance, and the plants eighteen inches aſunder in the rows, obſerving to do it in autumn, as before directed, and continue to trim them in the ſummer, for what they are intended; after they have continued three or four years in this nurſery, they may be tranſplanted where they are to remain, always obſerving to remove them in autumn where the ground is very dry; but on cold moiſt land it is better in the ſpring.

Theſe trees are very ſlow in growing, but yet there are many very large trees upon ſome barren cold ſoils, in divers parts of England.

YOAK, *or* YOKE, a frame of wood, fitted over the necks of oxen, whereby they are coupled together, and harneſſed to the plough.

Horſes and oxen are the animals uſed for drawing ploughs. Sometimes the one, ſometimes the other, and ſometimes both together. It is impoſſible to determine which of theſe is the moſt proper. This depends upon the kind of food moſt eaſily obtained, the kinds of work required, and the expence of breeding, or purchaſing. If the real labour is to determine this, without any other conſideration, then oxen are to be preferred; becauſe as they ſtand to the draught, they will overcome a reſiſtance which horſes will yield to.

As it cannot be determined, what kind of cattle are moſt proper for the plough; ſo neither can it be determined, what number is neceſſary. This depends upon the ſtrength of the cattle, and the nature of the ſoil. The number varies according to the work in which the plough is to be employed, and often according to the cuſtom of the place, and fancy of the farmer.

The methods of yoking cattle, in ploughs vary almoſt as much as the number uſed. Some of them at firſt ſight are ſo aukward, that it is needleſs to conſider them. The only thing worthy of being inquired into, is, whether the cattle ſhould be yoked in pairs, or in a line before each other? We ſhall therefore conſider the advantages and diſadvantages attending each way, and compare them together.

The moſt common way of yoking cattle in ploughs is in pairs. There are ſome diſadvantages attending this way that are obvious. In ploughing the furrows betwixt ridges, the land-cattle go upon the ploughed land, and tread it down with their feet: this, eſpecially if the land is wet, hurts it very much.

There is another diſadvantage very obvious. When there is but as much of the ridge unploughed as to allow the land-cattle to go upon it with difficulty, they are frequently either going into the oppoſite furrow, and thereby giving the plough too much land; or, which is worſe, they are juſtling the furrow-cattle upon the ploughed land.

To remove theſe inconveniencies that attend the ploughing with cattle yoked in pairs, ſome yoke them in a line before each other. It is obvious, that cattle yoked in this manner, going always in the furrow, neither tread upon the ploughed land, nor juſtle one another. In theſe reſpects the yoking the cattle in a line before each other, ſeems to have the advantage.

It is to be obſerved, however, that this method is not quite free from inconveniences. When examined, it may perhaps be found attended with as great inconveniencies as the other.

When cattle are yoked in a line, they go all in the furrow. This makes it neceſſary to give the plough more land than ordinary, either by the ſoke or the muzzle: for if this be not done, the head and ſoke being in the ſame direction with the beam, and the cattle yoked to the middle of it, the plough will directly follow the cattle, without taking any thing off from the land. Now, it is inconvenient to be obliged to give the plough land either by the ſoke or muzzle; for, when the ſoke is turned out of the plane of the beam, it makes the plough heavy to draw; and when the muzzle puts the draught too much to one ſide of the beam, it prevents the plough from going upright.

upright. The yoking the cattle in pairs is attended with none of theſe inconveniences: for, in this caſe, the quantity of land, which the plough has naturally, when right made, is ſufficient to make it take off a proper furrow.

There is another inconveniency that attends yoking cattle in a line, ariſing from the nature of the animals. Horſes and oxen, like men, love their eaſe, and are diſpoſed to throw the burden upon their fellows. This they have a better opportunity of doing when yoked in a line before each other, than when yoked in pairs. When yoked in a line, each pulls by the traces of the one behind him; and therefore, though it may be known when the foremoſt neglects his work, by the ſlackening of his traces, yet it cannot be known when any of the reſt neglect their work; for though one of them does this, yet by the pulling of the one before him his traces may be fully ſtretched. But this is eaſily diſcovered, when the cattle are yoked in pairs; for then every one of them has a ſeparate draught. The goadman or driver knows, by the poſition of the yokes or croſs-trees, whenever one of them does not draw equally with his fellow; and the ploughman perceives, by the going of the plough, whenever any of the two pairs does not draw equally with the other: for if the pair that goes foremoſt neglect their work, the plough is pulled out of the ground; and if the pair that go hindmoſt neglect their work, the plough is pulled in too deep. The reaſon is obvious; the plough is made to go at a proper depth, when the two forces by which different directions are given the plough, act at the ſame time. If one of them then ſhould ceaſe to act, the plough cannot go right. If the foremoſt pair ſhould ceaſe to draw, the plough having too little eard for the direction of the draught of the hindmoſt pair, will come out of the ground: and if the hindmoſt pair ceaſe to draw, the plough having too much eard for the direction of the draught of the foremoſt pair, will go in too deep. This does not hold in an ox-plough: for as the ſoam by which the foremoſt pair draw is fixed to the yoke of the hindmoſt pair, the whole force applied to the plough is in the ſame direction; and therefore, though any of the pairs ceaſe to draw, there is no alteration in the going of the plough.

There is yet another inconveniency that attends the common way of yoking cattle in a line before each other. When the fore cattle are all yoked to the traces of the hindmoſt, it is obvious, that as the beam, to which the draught is fixed, is much lower than his ſhoulders, by which the reſt pull, ſuch a weight muſt be laid upon his back or ſhoulder, as muſt render him incapable of giving any aſſiſtance. Beſides, as the whole force is applied in the direction of the traces of the hindmoſt horſe, it cannot have ſuch influence on the plough, as when a part of it is in a direction more horizontal. When a body is to be moved forward in any direction, the nearer that the direction of the force applied approaches to the direction of the body, it acts with greater influence. And therefore, as the plough moves horizontally, and as the direction of the united draught of a plough with the cattle yoked two abreaſt, is more horizontal than the direction of the draught in a plough with cattle yoked in a line, the ſame force applied will have greater influence.

When theſe two different ways of yoking cattle in ploughs are thus conſidered and compared together, it is difficult to determine which ought to be preferred. Each of the two ſeems preferable to the other in a certain ſituation. When the land is ſtiff and the labour ſevere, the yoking the cattle in pairs ſeems preferable, as it is certainly the ſtrongeſt draught; and when the land is wet, and in danger of being much hurt by the treading of the cattle, the yoking them in a line before each other ſeems preferable; as thereby they are confined to the bottom of the furrow, which is the firmeſt part of the land, and prevented from doing harm.

When a perſon uſes two or more ploughs, it is a very proper way to have one with the cattle yoked in a line, and the reſt with the cattle yoked in pairs. The ploughs with the cattle yoked in pairs continue as long as the land-cattle have room to go eaſily upon the firm land; and the plough with the cattle yoked in a line, follows, and clears up the furrows. In this way the cattle yoked in pairs do no damage, and the cattle yoked in a line are never uſed but where they are of real benefit.

To perſons that incline to yoke the cattle in a line before each other, it will not be amiſs to point out a way to remove the inconveniency laſt mentioned, and ſhow how the cattle may be yoked ſo as to lay no additional weight on the back or ſhoulders of the hindmoſt horſe, and to make the direction of the draught more horizontal. This is done by making the traces of the horſe next to the plough but one very long, and fixing them, not to the ſhoulders of the horſe behind him, but to the croſs-tree, and by fixing the traces of the horſe before him, not to his ſhoulders, but to his traces at the place where the back-rope is fixed. By this the hindmoſt horſe is delivered from the burden laid upon him in the other method, as his draught is entirely independent of that of the reſt. There is indeed ſome weight laid upon the horſe immediately before him, to whom the others are yoked. But this is but ſmall; for his traces are nearly in the ſame direction with theirs, and they are yoked to him at a place lower than his ſhoulders. By this, likewiſe, the direction of the united draught is more horizontal, when there are three or more horſes yoked; it is even more horizontal than when the cattle are yoked in pairs. In a four-horſe plough yoked in pairs the two forces are equal; but in a four horſe-plough, yoked in this manner, the force moſt horizontal is to the other, as three to one.

The traces of the horſe hindmoſt but one being long, will incommode the hindmoſt horſe in turning, if they have nothing to ſupport them. To prevent this, two links muſt be fixed to the ſhoulders of the hindmoſt horſe, and the traces paſſed through them; the links long enough to allow the traces to be ſtretched.

When two horſes are ſufficient for the draught, the yoking them in this manner deſcribed for the two hindmoſt, removes alſo the ſecond inconvenience mentioned, that attends the yoking the cattle in a line: for the ploughman diſcerns, by the going of the plough, when any of them neglect their work, in the ſame manner as when there are four horſes in the plough yoked in pairs.

The ordinary method of yoking oxen, is attended not only with all the inconveniencies of yoking cattle in pairs, but alſo with the laſt-mentioned inconveniency, of yoking cattle in a line. For the ſoam, by which the foremoſt cattle draw, is fixed to the yoke of the hindmoſt pair. Their yoke being higher than the beam, a great weight is laid upon their necks by the drawing of the foremoſt cattle.

n conveniency may be removed, and the oxen yoked in ſuch a manner, as to give two directions to the plough, as is done when horſes are yoked in pairs; by which the draught

draught will likewiſe be made ſtronger. To do this, the ſoam of the pair immediately before the hindmoſt muſt be fixed, not to their yoke, but to the beam; and, to prevent this ſoam from incommoding the hindmoſt in turning, a link muſt be fixed to their yoke for it to paſs through, the link long enough to allow the ſoam to be fully ſtretched. When there are more than two pair in the plough, as is moſt common, the largeſt-ſized cattle ſhould be placed next the plough, and the ſmalleſt-ſized immediately before them. For the lower that the yoke of theſe laſt is placed, the nearer will the direction of their ſoam be to the ſoam of thoſe before them; and thereby the leſs weight laid upon their necks. This method of placing the cattle is contrary to the ordinary way: for it may be obſerved, that the ſmalleſt-ſized oxen are always placed next to the plough. But theſe different ways of placing the cattle are both founded upon the ſame reaſon: for the ſmalleſt ſized oxen are placed next the plough in the ordinary way of yoking, that ſo their yoke, to which the ſoam of the pair before them is fixed, may be as low as poſſible: for the lower that it is placed, the nearer the directions of the two ſoams approach each other, and the leſs weight is laid upon the necks of the hindmoſt pair. And, for the ſame reaſon, the loweſt-ſized oxen ſhould be placed in the middle, when yoked in the manner propoſed, that ſo they may be leſs incommoded by the pair before them.

If, in conſidering the moſt proper method of yoking cattle in ploughs, we had nothing in view but the ſtrength of the draught, and conveniency of the cattle; we would always recommend the yoking the cattle in ſuch a way, as to apply two forces to the plough in different directions. But as we muſt alſo have in our view the going of the plough, hence it becomes neceſſary to obſerve, that ſometimes it is an advantage, to have the draught of the whole cattle in the ſame direction.

In ploughing lea, where the ſward is tough, or any kind of land, where there are interruptions from roots or the hardneſs of the bottom; the plough, if two forces are applied to it in different directions, goes very unſteadily, ſometimes too deep, and at other times too ſhallow; and is very difficult to manage. The reaſon is obvious: when the plough meets with ſuch interruptions, as tend to make it go deeper, or ſhallower, than its ordinary way of going; if at the ſame time, the force that acts contrary to the interruption ceaſes, then the plough, in ſpite of all the attention of the ploughman, will either ſtart out of the ground, or go in too deep, according to the tendency of the interruption. But when there is only one force acting upon the plough, it is, in ſome reſpect, like the wheeled plough; it goes ſteadily and at a certain depth; at leaſt, it is not ſo difficult to manage it, as when there are two forces acting in different directions: for though ſome of the cattle, at the time when the interruption is given, ſhould ceaſe to draw, yet the draught continues ſtill in the ſame direction, and the ploughman has only the alteration occaſioned by the interruption, to rectify. Every perſon knows, that an ox-plough goes much more ſteadily than a horſe-plough: and this is occaſioned, not only by the nature of the animals, oxen being more ſteady in drawing than horſes; but alſo by the manner of yoking them, oxen being yoked in ſuch a manner, as that one force only is applied to the plough.

Thus it appears, that no abſolute determination can be given, which of theſe two ways of yoking cattle in ploughs is to be preferred. Men muſt weigh the advantages and diſadvantages attending each way, and determine according to circumſtances. If the land is of a kind not eaſily ploughed, the cattle not well trained, and the ploughmen not expert, the work will be beſt performed, if there is only one force applied to the plough. But if the land is eaſily ploughed, that is, has few things in it to incommode the plough in going; if the cattle are well trained, and the ploughmen expert, the work will be well enough performed, and the labour leſs ſevere upon the cattle, if two forces are applied to the plough in different directions.

YOAK *of land*, the quantity of land which a yoak of oxen might plough in a day.

INTRODUCTION.

BEFORE we proceed to enumerate the work neceſſary to be done in the kitchen, fruit, and flower-gardens, as well as in the nurſery, it will be proper to give ſome directions for laying out theſe incloſures; conſider the nature of the ſoil beſt adapted to bring their reſpective products to perfection; and lay down a few cautions requiſite to enſure ſucceſs.

Neither the huſbandman, nor the country gentleman of moderate fortune, who prefers utility to oſtentatious ſhow, can ſet about an eaſier or more profitable branch of culture, than that of the kitchen and fruit garden, which may very properly be intermixed, and occupy one and the ſame ſpot of ground, ſince they both require a good, deep ſoil, and nearly the ſame expoſure. The walls which incloſe the kitchen garden, in order to ſecure its product, will be extremely ſerviceable for fruit: and, if elegance ſhould be ſtudied, this united garden may ſtill be placed out of view from the dwelling-houſe.

The chief things to be conſidered in the choice of a ſpot of ground for a kitchen and fruit garden are, the ſituation, the ſoil, the conveniency of water, the extent moſt proper to be incloſed, and the manner of incloſing it, and laying it out.

If the huſbandman can chooſe his ſoil and ſituation for a garden, the former ſhould be rich, rather ſtiff than light, and conſiderably deep. Nor is a moderate degree of moiſture here by any means an objection. The ſituation ſhould be nearly level: becauſe heavy rains would waſh away the richeſt part of the mould, if the declivity were conſiderable. If he has not a level ſpot near his houſe, the ground intended for the garden may be made into flats with terraces ſupported by ſtrong walls, which will become uſeful for fruit trees. A gentle inclination may be preſerved, to anſwer Mr. Miller's idea of having one part of dry ground for early crops, and the lower part for late crops, in order that the kitchen may be the better ſupplied throughout the ſeaſon with the various ſorts of herbs, roots, &c.

He ſhould not be diſcouraged at ſome ſeeming diſadvantages to which his ſoil and ſituation may expoſe him; for no difficulty is ſo great, but that it may be overcome by care, induſtry, and perſeverance. Of this we have a ſtriking inſtance in the following part of a paper which D. J. Beal read to the Royal Society, ſome years ago, with a view to the improvement of gardening in Scotland.

"I had, ſays he, ſeveral conferences with Sir Robert Murray (who was an honour to his country, and a bleſſing to the place where he abode) concerning eſculent and olitory gardens, and (under one) nurſeries of fruit-trees, and other uſeful vegetables in Scotland. I repreſented, that, almoſt within my memory, they are become the chief relief of England; that auſtere fruit has been found to yield the ſtrong and ſprightly liquor which reſembles the wine of the grape; that the return of gain from gardens is great and ſpeedy; and that nurſeries are neither a chargeable nor a burthenſome addition, but a motive of encouragement to perſevere in the nobleſt kind of agriculture. Sir Robert granted all I ſaid: and I am ſure he executed all that he could for the benefit of his own country, and of this. But, ſaid he, there are ſo many rocks, and ſuch bleak winds, in Scotland, that it can hardly draw in the ſame yoke with England, for gardens and orchards. I replied, that in Devonſhire and Cornwall they fence their gardens and orchards with Flanders furze and tall holly, from the ſea winds; that they have lofty firs and goodly pines in Scotland; and that New England, where the winds are as keen, and the ſnow and froſt as deep, and as long laſting as in many parts of Scotland, is nevertheleſs full of fruitful orchards. And if Scotland be farther in the north, yet Norway is rich in boſcage; and the ſeeds of the hemlock, fir, ſpruce, and cedar, from New England, Newfoundland, and Virginia, may perhaps rejoice in the exchange of Northern America for the north of this iſland.

"This, I told Sir Robert, I durſt undertake; that when Edinburgh and their chief towns and univerſities ſhall plant kitchen gardens, as we do now in England, they ſhall receive their grateful reward the firſt year, and bear the charges of their nurſeries abundantly, and ſo hold on, and within ſeven years ſecure their poſterity of the benefit, and delight themſelves with the fruit of their pleaſing labour.

"Now for fertilizing rocks, I made bold to repeat it often, that, within a day's journey of the heart of England, I could ſhew three gardens, the beſt that I have ſeen for flowery beauties, Engliſh ever-greens, and ſallads all the winter long; all theſe on a hard rock, in moſt places but one foot deep under earth, in ſome two, and in very few three, with very lofty hills cloſe to the ſouth ſide, the declivity of the gardens due north, and the rock perfectly bare next to the walls on the north ſide. I likewiſe ſaw rich hop yards in the ſame caſe, but in deeper ground, next to the garden on the ſouth ſide: and theſe northern hop yards eſcaped many blaſts, which ſeized on the hop yards on the ſouth ſide of the hill. On the ſteep aſcent on the north ſide of one of theſe rocky hills, where no plough could come, I ſaw a gentleman ploughing up the ſhallow turf with a hand-plough, for flax; and I ſaw good flax grow there, to the largeneſs of a village-field. His hand-plough had a ſtem of aſh, or ſally, about ſeven feet long, and a plate at one ſide near the end, to turn the turf; a coulter to be let out ſhorter or longer, to cut the turf four, five, or more inches deep, as the land permitted, and a ſmall iron wheel. This hand-plough the maſter and the man, by turns, drove before them with a walking ſpeed; having leathern aprons before them, to ſave their cloaths. For the cauſes of this hardy fertility, let philoſophers account. I am ſure of the truth of what I write.

"It is no hard taſk to ſhovel down the ſhallow and moſſy turf, from the deepeſt declivities of rocks, into places where it may have a receptacle or ſtay, and there, with the ſpade to mix and impregnate it with compoſt

for gardens or vineyards. There too the tenth part of an acre in gardening may yield more profit, than ten acres of ordinary tillage in a corn field." *Philoſophical Tranſactions*, numb. 116.

On the other hand, we have many proofs that wet, and even very marſhy, grounds have been converted into excellent kitchen gardens, after they have been drained. Such was, formerly, all that large part of Paris which ſtill retains the name of *le marais* (the marſh;) and ſuch were, evidently, ſeveral of our moſt profitable gardens around London. The marquis of Turbilly has given us farther inſtances of this truth in ſeveral of his noble improvements; and the Memoirs of the truly patriotic Society of Berne remark very juſtly, that all legumes and pot herbs thrive perfectly well in the black, rich, moiſt, and ſomewhat riſing grounds, which moſt commonly ſkirt the borders of marſhes.

As warmth is eſſentially neceſſary to a garden, it is adviſable that the expoſure of the ground intended for this purpoſe be to the ſouth-eaſt or ſouth; and that it be protected from the north and north-eaſt either by high grounds, or plantations of lofty trees at a ſmall diſtance. Fruit-trees require to be likewiſe protected from the ſouth-weſt and weſt, which are apt, in the autumn, to ſhake the fruit.

The huſbandman ſhould here ſpare no trouble or expence to render his ſoil of a proper quality and depth: and if it be not naturally ſo, he muſt have recourſe to one or other of the methods practiſed for the improvement of ſoils, according to the nature of his ground.

Whatever the ſoil be, the mould in which the plants are to live and thrive, ſhould be deep enough to afford their roots full room to extend themſelves. It appears by ſeveral experiments, that the roots of many plants, not excepting even annuals, pierce to the depth of eighteen inches, and more. To allow therefore a ſufficiency of room, though perhaps more than may be really wanted, a depth of three feet of good mould ſhould be allotted them here: and if the ſoil underneath is clay, or retentive of water, which would be apt to chill the roots of plants, it will be right to exceed even this depth.

Trenching is the moſt effectual way to obtain a conſiderable depth of well looſened mould. The common method of doing this, when the ſoil underneath is clay, is to begin with digging a trench four or five feet wide, either along or acroſs the whole ground; then to lay in the bottom of it, about half a foot thick, long dung, fern, leaves of trees, rotten ſticks, weeds, or any other ſuch like traſh, to rot and keep the ſoil from binding; then to fill this up with the earth dug out of the next adjoining trench, laying uppermoſt the ſpits that were loweſt, and ſo to continue till the work is finiſhed, without ever going deeper than juſt to the clay, though the ſurface be never ſo ſhallow. But if the clay be dug into, and part of it be turned up and mixed with the other earth, its bad qualities will ſoon be corrected by the influences of the air, rain, and one winter's froſts; it will become good and fertile mould, and the depth of the ſtaple will be increaſed thereby, eſpecially with the addition of a little drift ſand, coal, or other aſhes. The beſt time for trenching of land, that it may receive the benefit of being well mellowed, is the beginning of winter; when alſo, being moiſt, it is eaſy to dig.

When the mould on the ſurface is but ſhallow, and lies on a bed of ſand, gravel, or looſe earth, it will be adviſable to lay a layer of ſtiff earth, inclining to clay, at the bottom of the trench. This will be more eſpecially neceſſary for the growth of trees, or plants whoſe roots naturally pierce deep: for by means of this earth, thoſe roots will ſpread horizontally in the mould, inſtead of ſtriking down, as they would otherwiſe do, into barren earth, which would immediately make the trees decay and become ſtinted. And another advantage attending this method will be, that as water cannot ſo eaſily deſcend through this ſtiffer ſoil, the earth will be thereby preſerved in a ſo much moiſter ſtate; yet even here the clay ſhould not be ſuch as is impervious to water; for this, unleſs it lie very deep, would be attended with as bad conſequences as the other extreme.

The general practice of gardeners is regularly to trench their ground, and lay it rough in the winter, without ſufficiently conſidering the quality of the ſoil, or the nature of the earth which lies underneath. But a little reflection would convince them of their error. Let us, in this light, ſee what is the effect of trenching various ſoils. If the ground is naturally light, and lies on a bed of ſand or gravel, it is to be feared that every ſubſtance brought to improve the ſoil, together with its fineſt and richeſt particles, will be carried down into that ſand or gravel. Does not too frequent trenching contribute to this loſs? as does likewiſe laying the ſurface rough in the winter: for the rains waſh the finer mould into the hollow places, from whence the depth of the ſoil being leaſt there, it is moſt readily carried down into the looſe earth underneath. If the ſoil underneath is ſtiff, frequent trenching is proper in order to bring back to the ſurface the rich mould that has been waſhed down: and if it be naturally ſtrong, the laying of it rough in the winter is an advantage, becauſe the winter's froſts will moulder its tough ſtrong particles.

This method of preparing the ground is, undoubtedly, expenſive: but its fertility afterwards will yield an ample reward.

Plenty of water is abſolutely neceſſary in this garden, and therefore great care ſhould be taken to provide it, in ſuch manner that it may be come at as eaſily as poſſible. If a ſufficient ſupply of it can be obtained from the neighbouring grounds, two or three baſons ſhould be made in different parts of the garden, if it be a large one; for when the water is to be carried to a conſiderable diſtance, the expence attending this neceſſary buſineſs will be great, and there will be danger of the plants ſuffering for want of it; labourers being very ſparing of their work, eſpecially when it is toilſome, unleſs they are well looked after. The ſize of theſe baſons ſhould be proportioned to the quantity of water that will be wanted, or with which they can be ſupplied: but their depth ſhould not exceed four feet, for fear of accidents, if people ſhould chance to fall into them: beſides which, deep water is not ſo well warmed and tempered with the ſun and air, as when it is ſhallow.

The methods uſed for collecting and preſerving of water in ponds or reſervoirs in the field, are equally applicable to the making and repleniſhing of theſe baſons in the garden. But it will be proper here to add the following more particular cautions and inſtructions of Mr. Miller, who, after obſerving, that the beſt time of the year

BRITISH MUSEUM 15 64 JUN

year for lining theſe baſons with clay, particularly in looſe or ſandy land, and for afterwards covering that clay with a thick layer of coarſe gravel, is in autumn, when the ſun is declining, and the weather temperate, adviſes, "as a farther means of ſecuring this clay from being cracked by the heat of the ſun, or by froſt, to lay upon the rim or top of it, around the ſides of the baſon, a ſtratum of ſand, then a ſtratum of good earth, and upon this a layer of thick turf. The graſs thus laid will root in the mould underneath, and bind the whole firmly together: and it ſhould be laid as far down the inſide of the baſon, as the water is apt to ſhrink to, that no part of the clay may be wholly expoſed to the weather.

"No trees or ſhrubs ſhould be ſuffered to grow near theſe baſons, leſt their roots ſhould penetrate into them, and thereby occaſion holes through which the water would find an eaſy paſſage. Neither ſhould theſe reſervoirs be made near to tall trees, becauſe the ſhaking of them, by violent winds, would be apt to looſen and crack the clay.

"In countries where clay proper for this purpoſe cannot be eaſily had, theſe baſons are frequently lined with chalk beaten into fine powder, and made into a ſort of mortar, which is rammed down and worked very hard and firm all over their inſide. This cement holds water very well, if the pond be not ſuffered to remain too long dry: for when this happens, the ſun and wind are apt to crack the chalk, and theſe cracks generally extend through its whole thickneſs, ſo as to let out the water.

"Some line theſe ponds with bricks laid in terras, which is a good method where the ground is very looſe and ſandy; becauſe when theſe walls are well built, the ſurrounding earth may be rammed down cloſe to them, ſo as to prevent its falling away, or ſettling from them. But, as heat is apt to crack the terras, no part of this lining ſhould be left long dry and expoſed.

"Others again uſe for this purpoſe a cement of powdered tile and lime, two thirds of the former to one third of the latter, beaten well together, and worked up with but little water: for the ſtiffer it is, and the more it has been beaten, the better it will be. With this cement they cover the ſurface of the walls of baſons about two inches thick, laying it very ſmooth, and taking great care that no ſticks, ſtraws, or ſtones be mixed with it. This is generally done in dry weather; and as ſoon as the whole inſide of the baſon has been plaſtered in this manner, it is rubbed over with oil or bullock's blood, and the water is let in immediately after. This cement has the property of hardening under water, ſo as to be equal to ſtone; and it will continue as long ſound."

Where a ſupply of water for baſons and ponds cannot be obtained, wells muſt be dug; and it is generally adviſed, that the water taken out of them be expoſed to the ſun and air for ſome time, before it is uſed, becauſe, ſays Mr. Miller, the rawneſs of this water, when freſh drawn, is not agreeable to the growth of vegetables.

The ſize of this garden ſhould be in proportion to the wants of the family; but with a much larger allowance of ground than is uſually allotted, in order that the plants may be benefited by ſtirring the earth between them whilſt they grow. The great and manifeſt advantages of this practice, eſpecially in the culture of pulſe and garden plants, have been ſo evidently ſhewn by numbers of experiments related in the former parts of this work, that we cannot but again recommend it here as an object of high importance.

It ſhould be incloſed with a wall, either of brick or ſtone; but brick is beſt, for the greater conveniency of nailing up the fruit-trees which are to be planted againſt it. The thickneſs of theſe walls ſhould be proportioned to their height, which ſome run up to twelve or fourteen feet, or more: but nine or ten will be enough for almoſt any kind of fruit; and in this caſe thirteen inches, that is to ſay, a brick and a half, will be a ſufficient thickneſs; though two bricks will be better, for duration. Their inſide ſhould be built as ſmooth as poſſible, and, to ſtrengthen them againſt high winds, piers ſhould be run up with them, at the diſtance of about twelve or fourteen feet from each other, according to the uſual extent of the fruit-trees for which they are intended. As to pears, which ſpread very wide, and frequently grow much above the height here mentioned, they do not require the aſſiſtance of a wall; unleſs it be ſome of the lateſt winter ſorts, and theſe the curious, who will be at the expence, may plant againſt walls built on purpoſe for them. Theſe piers may project ſix or eight inches on the outſide of the wall, for the ſake of greater ſolidity; and they ſhould advance about four inches on the inſide, for the convenience of fixing to them trelliſes, by building the wall on arches; and planting the trees at thoſe arched places, as Mr. Hitt adviſes, the trees will be thereby enabled to extend their roots underneath the wall; which will prove very advantageous to their growth.

If the quantity of walling which ſurrounds the kitchen garden be too little to furniſh the deſired ſupply of fruit, a croſs wall may be built through the middle of this ground; or, where the ſize of the garden will admit of it, there may be two croſs walls: but theſe walls muſt not, by any means, be leſs than eighty or a hundred feet aſunder. More will be yet better.

Mr. Miller is clearly of opinion that the beſt aſpect for walls in England, is to have one point to the eaſtward of the ſouth; becauſe theſe will enjoy the benefit of the morning ſun, and be leſs expoſed to the weſt and ſouth-weſt winds (which are very injurious to fruits in this country) than thoſe which are built due ſouth. "I knows, ſays he, that many perſons object to the turning of walls the leaſt point to the eaſt, on account of the blights which they think come from that quarter in the ſpring: but from many years experience and obſervation, I can affirm, that blights as often attack thoſe walls which are open to the ſouth-weſt, as thoſe which are built to any other aſpect; and I believe thoſe who will be at the trouble of obſerving for ſeven years, which aſpected walls ſuffer moſt from blights, will find thoſe which are built with a point to the eaſtward of the ſouth, as ſeldom blighted as thoſe which are turned to any other aſpect; therefore in the contrivance of a kitchen garden, there ſhould be as great a length of theſe walls built as the ſituation of the ground will admit.

"The next beſt aſpect is due ſouth; and the next to that ſouth-eaſt, which is preferable to the ſouth-weſt, for the reaſons before aſſigned: but as there will, for the moſt part, be ſouth-weſt and weſt walls in every garden, theſe may be planted with fruits which do not require ſo much heat to ripen them, as thoſe deſigned

for

for the beſt walls; but wherever there are north walls, thoſe will only be proper for baking-pears, plums, and morello cherries for preſerving; or ſome duke cherries may be planted againſt theſe walls, to ſupply the table till peaches, nectarines, and plums are ripe."

In whatever manner the walls are made, this garden ſhould be well ſheltered from the north and north-eaſt, by a diſtant plantation of high timber-trees, if nature has not otherwiſe provided a ſufficient defence from thoſe quarters.

In the diſtribution of this garden, particular care ſhould be taken to lay the walks out ſo as to obtain the greateſt convenience that can be for ſupplying each part of it with manure and water, and as eaſy acceſs as poſſible to its different quarters, which may be ſurrounded by a border planted with eſpaliers. The manner of forming eſpaliers will be directed when we come to ſpeak of the training of fruit-trees.

Theſe walks ſhould be firm enough to bear at leaſt the weight of a loaded wheel-barrow, and wide enough for the convenient carriage of whatever there may be occaſion to bring into this garden, or to carry out of it. Mr. Miller is againſt making them of gravel; becauſe, as it will very often be neceſſary to wheel manure, water, &c. upon them, they would ſoon be torn up and rendered unſightly; unleſs care be taken that the wheel be broad; or rather that it be a roller as wide as the diſtance between the ſides of the wheel-barrow.

For the ſame reaſon he rightly condemns turf-walks here, and adviſes, as the beſt for a kitchen garden, thoſe which are laid with a binding ſand. In effect, theſe are the eaſieſt kept of any: for when either weeds or moſs begin to grow, ſcuffling of them over with a Dutch hoe in dry weather, and raking them over a day or two after, will render them as clean as when they were firſt laid: or if they are covered with duſt taken from great roads, this will bind and become very firm.

If the ſoil is ſtiff and apt to retain water, narrow underground drains ſhould be made by the ſides of the walks, to carry off that wet: and where the ground is naturally moiſt, lime rubbiſh, flints, chalk, or any other ſuch material as can be procured with the leaſt expence, ſhould be laid at the bottom of theſe walks; or if neither of theſe can be had, the ſand ſhould be laid thick upon a bed of heath or furze, and the water will drain through this, ſo that the walks will be firm and good in all ſeaſons.

The ſame means will alſo help greatly to drain away the ſuperfluous moiſture of the whole ground, if the ſoil ſhould be naturally too wet; for if they are not ſufficient, more under-ground drains may be made acroſs different parts of the garden, according to its declivity: for moſt kitchen plants are hurt by too much moiſture in winter; and trees never produce good fruit when their roots lie in water.

If each quarter of the kitchen garden is to be encompaſſed by eſpaliers, the walks which divide thoſe quarters ſhould be wide enough to afford admittance to the warmth of the ſun, and to a free current of air. In this caſe they may be, as Mr. Miller directs, ſix feet wide in ſmall gardens, and ten or twelve in extenſive grounds. On each ſide of theſe walks, the eſpalier ſhould be planted in a border four or five feet wide; by which means the two eſpaliers will be far enough aſunder for their roots never to injure one another. Theſe borders may be ſown with ſmall ſallading, or any other herbs that do not continue long or root deep; ſo that no ground need be loſt, and the continual ſtirring and manuring of it for theſe productions will be of great ſervice to the roots of the trees.

The borders along the ſouth and other walls that have a good expoſure ſhould, in the opinion of this experienced gardener, be at leaſt eight or ten feet wide, in order to allow the roots of the fruit-trees that are planted againſt them full room to extend themſelves. Such of theſe as face the ſouth may be ſown for early crops of plants which do not root deep, and thoſe that are expoſed to the north will do for late crops: but no deep rooting plant, eſpecially peaſe and beans, ſhould ever be placed too near the trees; though moſt gardeners are apt to tranſgreſs greatly in this reſpect, as well to preſerve their crops in winter, as to bring them forward in the ſpring: both which ends might be anſwered equally well, and without prejudice to their fruit-trees, by making reed hedges in ſome of the warmeſt quarters, and ſowing cloſe to them their early peaſe, beans, &c. if ſuch fences are found to anſwer the purpoſe of forwarding their growth.

It is a general opinion, that plants which are ſheltered by walls, ſo as to be defended from nipping winds, and to have the additional warmth of the reflected heat of the wall, are leaſt liable to be deſtroyed by the winter's froſts; for which reaſon it is that early crops are moſt commonly in borders ſo ſituated. The ſun will undoubtedly give greater motion to the ſap of plants there, and they may, for this reaſon, ſeem to be the ſtronger. But if we conſider, that the walls yield no protection againſt the ſeverity of the night's froſt, and that the effect of this froſt muſt be moſt ſeverely felt by plants whoſe ſap is in the greateſt motion; we may rather fear that this ſituation, inſtead of being beneficial, may, in fact, counter-act the very end propoſed. To be ſatisfied of this fact, a gentleman ſowed ſome early peaſe in a border at the foot of a ſouth wall, and at the ſame time ſome others, of the ſame ſort, in an open field adjacent to the garden; and he found, that the latter were by much the leaſt damaged by the winter's froſts; nor did he perceive any great difference in the ſeaſon of their blooming.

A ſquare or an oblong form will be moſt agreeable to the eye: but it matters not, in other reſpects, what ſhape this garden is of; eſpecially as all groſs irregularities may eaſily be hid in the laying of it out. Thus, when this is done, any of the ſlips cut off by the garden-wall, may, if large enough, and well expoſed to the ſun, be ſet apart for a place to make hot-beds for early cucumbers, melons, &c. One would wiſh this ſpot to be as near as poſſible to the ſtables, for the convenience of ſupplying it with dung; and to have it without the wall is certainly moſt eligible, becauſe that will ſave a great deal of filth and litter in the garden, and remove from the noſe and eye an object which is not of the moſt pleaſing kind. If this ſlip is long enough to admit of an annual ſucceſſion of new beds during two or three years, they will be much better than when they are continued more than one year on the ſame ſpot: and as it will be abſolutely neceſſary to fence this melon ground, as it is called, round with a reed hedge, this may be ſo contrived as to be moved away in pannels, in ſuch manner that there will be no occaſion to ſhift any

thing

thing more than one of the croſs partitions, or fences, each year.

The importance of the precept particularly here, will juſtify our mentioning again, that the dunghill, ſet apart for this, or for any other purpoſe of gardening or agriculture, ſhould be carefully kept clear from weeds: for if weeds are ſuffered to ſcatter their ſeeds upon the dung, they will be brought into the garden or other cultivated ground, ſhoot up, damage every crop of uſeful plants, and occaſion a perpetual labour to extirpate them.

Another caution given by Mr. Miller, as abſolutely neceſſary to be obſerved, is, to carry off all the refuſe leaves and ſtumps of cabbages, the ſtalks of beans, and haulm of peaſe, as ſoon as they have done bearing; for the ill ſcent which moſt people complain of in kitchen gardens, is wholly occaſioned by thoſe things being ſuffered to rot upon the ground. The leaves of cabbages may be given to hogs or other animals, while they are freſh, and the reſt of the traſh may be thrown upon the dunghill, which it will help to enrich; or ſuch as will keep may be preſerved, to be thrown in the bottom of trenches, in that part of the garden which is to be trenched the following autumn.

And here we cannot help pointing out a neglect too common among gardeners, we mean, the letting their plants remain on the ground till they have ripened their ſeeds, and wither: not conſidering that whilſt a plant is in full ſap, it preſerves the earth in a looſe ſtate, probably by means of the moiſture perſpired from its roots; but if permitted to ſtand till its ſeed is ripe, or the plant withers, it leaves the impoveriſhed earth dry and hard, being itſelf become entirely void of ſap.

The moſt important points of general culture here conſiſts in good digging, keeping the ground clean, manuring the ſoil, and allowing proper diſtances between the plants, according to their ſeveral kinds and growth.

The kitchen garden, if it be rightly managed, is the moſt uſeful and profitable ſpot of ground, that either the country gentleman or farmer can cultivate. It is indiſpenſibly neceſſary to every family in the country, where the neareſt market-town is generally at too great a diſtance, and, at the ſame time, too poorly furniſhed with plants and roots, to afford a proper ſupply.

We ſhall conclude our obſervations on the kitchen garden, with laying down two rules neceſſary to be obſerved. 1. Never let the ground be crowded with more plants that it is able to nouriſh properly. 2. Never let any part of it remain unoccupied, for want of a due ſucceſſion of crops. By this means the maſter, whom we would adviſe to be always his own gardener, at leaſt ſo far as perſonally to direct and ſuperintend the whole management, may have his table conſtantly ſupplied with ſuch vegetables as he likes beſt; no part of his ground will lie uſeleſs, and each of its productions will be brought to perfection.

We have already obſerved, that the kitchen and fruit-gardens may very properly be intermixed, and occupy the ſame ſpot of ground. But notwithſtanding this, their various productions will require a very different treatment, though in the ſame incloſure: we ſhall therefore now proceed to conſider the latter, more particularly with regard to the method that ſhould be obſerved in

Making Borders for Peaches, Nectarines, Plums, Pears, Cherries, &c.

If the land be a ſtrong clay, take ſea ſand, if it may be eaſily had, if not any other ſand that is neareſt, and about one ſixth of the quantity of coal aſhes, that has been kept very dry; riddle them, but not too fine: for if ſome of the larger parts be left, they will diſunite the tough body of clay, make it more open and tender, and the finer parts that are more burnt, will increaſe its ſalts.

But if aſhes cannot be had, let one twelfth part of lime be added to the ſand. About one third part of the depth of the border ought to conſiſt of theſe ingredients; and in trenching the borders, there muſt be a layer of theſe, and a layer of the natural ſoil, from the bottom to the ſurface, in the above proportion, well mixed together.

If the ſoil of the borders be mixed with large pebbles, they muſt be picked out, and laid in the drains, where they will be uſeful. And as this kind of ſoil is generally of a looſe ſandy nature, it muſt be mixed with ſomething more ſtrong and binding, namely with clay, the tougheſt that can be got near the place. If it be taken from ditches whoſe ſoil is naturally a clay, or from ditches where there is ſometimes a current of water from arable fields of the ſame kind of ſoil, and there leaves its ſediment, it will anſwer the purpoſe very well.

At the bottom of the borders lay this clay ſix inches thick throughout, which will prevent the moiſture running out too faſt in the ſummer, as it is too apt to do in ſandy ground, eſpecially where there are proper drains made. When you have laid down the clay, and by that means formed a ſound bottom, let a ſufficient quantity of the clay be procured, and to each cart-load of the clay let there be added an equal quantity of the natural ſoil, three pecks of lime, or rather pigeons dung, and five of ſoot, and the whole well mixed together: if coal or wood-aſhes be uſed inſtead of ſoot, they muſt be made very fine, otherwiſe they will open this kind of ſoil too much; beſides, the finer they are made by burning, the more they will enrich the ground by ſalts.

If the borders are to be planted with trees where others have grown before, the depth and quality of the ſoil muſt be examined; and if it be deep enough, and compoſed of a mixture of ſand and clay, it will require to be trenched only, to draw off the too great quantity of moiſture, and a proper addition of lime or ſoot to be mixed with the ſoil.

But if the borders are deſigned for vines and figs, the natural ſoil ſhould be mixed with rubbiſh, as lime ſcraps, ſmall pieces of bricks, &c. for a foot deep at the bottom or more; for both the vine and fig-tree proſper beſt, and yield the fineſt fruit, in a dry ſoil, with a rock near the ſurface. If the land be ſandy, the lime ſcraps, &c. may be omitted, and only the ſoot, &c. added, as before directed.

It will be neceſſary to obſerve in trenching all borders, to pick out all the roots of bindweed, common thiſtle, and all other weeds whoſe roots ſtrike deep into the earth; but the roots of couch-graſs, &c. which run near the ſurface, may be buried at the bottom of the trenches, which will effectually deſtroy them without any further trouble.

When

When these, or, indeed, any borders are first made, they should be raised three or four inches above the height they are designed to continue; for they will settle so much, at least, in a year's time. Those which are ten feet broad, let them have a descent of six inches from the wall, and others in proportion to their breadth: four feet broad will be sufficient for borders made for vines only.

The Flower *or* Pleasure-Garden.

The flower-garden being intended solely for ornament and pleasure, a short account only of it will be given here, as the principal design of this work is utility.

The flower-garden should be made near the back-front of the house, from whence a descent of six or seven steps will finely embellish the whole. Proper room should be allowed for a lawn of sufficient extent, which, if it be the first object that strikes the sight, will have a very pleasing effect.

Mr. Miller very justly observes, that the great art of laying out gardens for pleasure, consists in adapting their several parts to the natural position of the ground, so as to have as little earth as possible to remove, which is often one of the greatest expences that attends the making of gardens.

The boundaries of these gardens, whatever they are fenced with, should be carefully concealed with plantations of flowering shrubs, intermixed with laurels and other ever-greens to cover the fences, which have a disagreeable appearance, when they are left naked and exposed. Nor should all the boundaries be seen from any one point of view; and if the country around affords a variety of pleasing prospects, it will be right to bound the pleasure-garden with an ha-ha ditch and wall, to lay these views open to sight.

The Nursery.

It is not our intention here to speak of those large and extensive nurseries, where all kinds of plants, trees, and shrubs, are raised for sale; but a nursery that is absolutely necessary for su h country gentlemen as are desirous of raising plants, trees, &c. for themselves. Two or three acres of land employed this way may well be sufficient for the most extensive designs; and one acre will be full enough for those of moderate extent. And such a spot of ground may be always employed for sowing the seeds of foreign trees and plants; and also for raising many sorts of biennial and perennial flowers, to transplant into the borders of the pleasure-garden; and for raising many kinds of bulbous-rooted flowers from seeds, whereby a variety of new sorts may be obtained annually, which will sufficiently compensate for the trouble and expence; and, at the same time, afford a very agreeable entertainment to gentlemen who are fond of these innocent amusements.

Such a nursery as this should be conveniently situated for water; for where that is wanting, a necessary expence will be incurred by the carriage of it in dry weather. It should also be as near the house as can conveniently be admitted, in order to render it easy to visit it at all times of the year; because it is absolutely necessary that it should be under the inspection of the master, who must delight in it, or there will be very little hopes of success. The soil of this nursery should also be good, and not heavy and stiff; for such land will be very improper for sowing most sorts of seeds; because, as this will retain the moisture in the spring and winter, so the seeds of most tender things, especially those of flowers, will, if sown early, rot in the ground. Therefore, where persons are confined to such land, a good quantity of sand, ashes, and other light manures, should be buried, in order to separate the parts, and pulverise the ground; and if it be thrown up in ridges to receive the frost in winter, it will be of great service to it; as will also the frequent forking or stirring of the ground, both before and after it is planted.

Let the ground be always kept free from weeds; for if these are permitted to grow, they will rob the young trees of their nourishment. Another principal caution is to dig the gound between the young plants at least once a year, to loosen it, and give room for the young fibres of the roots to strike out. But if the ground be stiff, it will be the better if the digging be repeated twice a year, viz. in October and March; which will at once promote the growth of the plants, and prepare the roots for transplanting.

The part intended for the flower-nursery should be well situated to the sun, and defended from strong winds by plantations of trees, or buildings: at the same time the soil should be light and dry, which must always be observed, especially for bulbous-rooted flowers.

In this nursery the off-sets of all bulbous-rooted flowers, seedling auriculas, polianthuses, anemonies, carnations, &c. should be planted, and continue there, till they become blowing roots, when they should be removed into the pleasure-garden.

You may also, in this ground, raise the several sorts of bulbous-rooted flowers from seeds, by which means new varieties may be obtained; but most people are discouraged from setting about this work, from the length of the time before the seedlings will come to flower: but it should be remembered, that after a person has once begun, and constantly continued sowing every year, after the parcel first sown has flowered, the regular succession of them coming annually to flower, will not render this method so tedious as it at first appears.

Orchard.

It is a rule among gardeners, that those orchards thrive best which lie open to the south, south-west, and south-east, being screened from the north, and have the soil dry and deep.

In planting of an orchard, great care should be had to the nature of the soil, that such trees as are adapted to grow upon the ground intended to be planted may be chosen, otherwise there can be little hopes of their succeeding; and it is for want of rightly observing this method, that we see, in many countries, orchards planted which never arrive to any tolerable degree of perfection, their trees starving, and their bodies either covered with moss, or the bark cracks and divides; both which are evident signs of the weakness of the trees; whereas, if instead of apples, the orchard had been planted with pears, cherries, or any other sort of

of fruit to which the ſoil had been adapted, the trees might have grown very well, and produced great quantities of fruit.

As to the poſition of the orchard, if you are at full liberty to chuſe, a riſing ground, open to the ſouth-eaſt, is to be preferred; but we would by no means adviſe to plant upon the ſide of an hill, where the declivity is very great; for in ſuch places the great rains commonly waſh down the better part of the ground, whereby the trees would be deprived of proper nouriſhment; but where the riſe is gentle, it is of great advantage to the trees, by admitting the ſun and air between them, better than it can upon an entire level; which is an exceeding benefit to the fruit, by diſſipating fogs, and drying up the damps, which, when detained among the trees, mix with the air, and render it rancid: if it be defended from the weſt, north, and eaſt winds, it will alſo render this ſituation ſtill more advantageous; for it is chiefly from theſe quarters that fruit-trees receive the greateſt injury: therefore, if the place be not naturally defended from theſe by riſing hills, which is always to be preferred, then you ſhould plant large growing timber-trees at ſome diſtance from the orchard, to anſwer this purpoſe.

You ſhould alſo have a great regard to the diſtance of planting the trees, which is what few people have rightly conſidered: for if you plant them too cloſe, they will be liable to blights; and the air, being hereby pent in amongſt them, will cauſe the fruit to be ill-taſted, having a great quantity of damp vapours from the perſpiration of the trees, and the exhalations from the earth mixt with it, which will be imbibed by the fruit, and render their juices crude and unwholeſome.

Wherefore we cannot but recommend the method which has been lately practiſed by ſome particular gentlemen with very great ſucceſs; and that is, to plant the trees fourſcore feet aſunder, but not in regular rows. The ground between the trees they plough and ſow with wheat and other crops, in the ſame manner as if it were clear from the trees; and they obſerve their crops to be full as good as thoſe quite expoſed, except juſt under each tree, when they are grown large, and afford a great ſhade; and, by thus ploughing and tilling the ground, the trees are rendered more vigorous and healthy, ſcarcely ever having any moſs, or other marks of poverty, and will abide much longer, and produce better fruit.

If the ground in which you intend to plant an orchard has been paſture for ſome years, then you ſhould plough in the green ſward the ſpring before you plant the trees: and, if you will permit it to lie a ſummer fallow, it will greatly mend it, provided you ſtir it two or three times, to rot the ſward of graſs, and prevent weeds growing thereon.

At Michaelmas you ſhould plough it pretty deep, in order to make it looſe for the roots of the trees, which ſhould be planted thereon in October, provided the ſoil be dry; but, if it be moiſt, the beginning of March will be a better ſeaſon.

When you have finiſhed planting the trees, you ſhould provide ſome ſtakes to ſupport them, otherwiſe the wind will blow them out of the ground; which will do them much injury, eſpecially if they have been planted ſome time; for, the ground at that ſeaſon being warm, and for the moſt part moiſt, the trees will very ſoon puſh out a great number of young fibres: which, if broken off by their being diſplaced, will greatly retard the growth of them.

In the ſpring following, if the ſeaſon ſhould prove dry, you ſhould cut a quantity of green turf, which muſt be laid upon the ſurface of the ground about their roots, turning the graſs downward; which will prevent the ſun and wind from drying the ground, whereby a great expence of watering will be ſaved: and, after the firſt year, they will be out of danger, provided they have taken well.

Whenever you plough the ground between theſe trees, you muſt be careful not to go too deep among their roots, leſt you ſhould cut them off, which would greatly damage the trees: but, if you do it cautiouſly, the ſtirring of the ſurface of the ground will be of great benefit to them; though you ſhould obſerve never to ſow too near the trees, nor ſuffer any great rooting weeds to grow about them, which would exhauſt the goodneſs of the ſoil, and ſtarve them.

If, after the turf which was laid round the trees be rooted, you dig it in gently about the roots, it will greatly encourage them. There are ſome perſons who plant many ſorts of fruits together in the ſame orchard, mixing the trees alternately; but this is a method which ſhould always be avoided; for hereby there will be a very great difference in the growth of the trees, which will not only render them unſightly, but alſo the fruit upon the lower trees ill taſted, by the tall ones overſhadowing them; ſo that, if you are determined to plant ſeveral ſorts of fruits on the ſame ſpot, you ſhould obſerve to place the largeſt growing trees backwards, and ſo proceed to thoſe of leſs growth, continuing the ſame method quite through the whole plantation; whereby it will appear at a diſtance in a regular ſlope, and the ſun and air will more equally paſs through the whole orchard, that every tree may have an equal benefit therefrom.

The ſoil of your orchard ought to be mended once in two or three years with dung, or other manure, which will be abſolutely neceſſary for the crops ſown between; ſo that where perſons are not inclinable to help their orchard, where the expence of manure is pretty great; yet, as there is a crop expected from the ground beſides the fruit, they will the more readily be at the charge upon that account.

In making choice of trees for an orchard, you ſhould always obſerve to procure them from a ſoil nearly a-kin to that where they are to be planted, or rather poorer; for, if you have them from a very rich ſoil, and that wherein you plant them is but indifferent, they will not thrive well, eſpecially for four or five years after planting; ſo that it is a very wrong practice to make the nurſery, where young trees are raiſed, very rich, when the trees are deſigned for a middling or poor ſoil. The trees ſhould alſo be young and thriving; for, whatever ſome perſons may adviſe to the contrary, yet it has always been obſerved, that though large trees may grow, and produce fruit, after being removed, they never make ſo good trees, nor are ſo long-lived, as thoſe which are planted while young.

Theſe trees, after they are planted out, will require no other pruning but only to cut out dead branches, or

such as croſs each other, ſo as to render their heads confuſed and unſightly: the too often pruning them, or ſhortening their branches, is very injurious; eſpecially to cherries and ſtone-fruit, which will gum prodigiouſly, and decay in ſuch places where they are cut: and the apples and pears, which are not of ſo nice a nature, will produce a greater quantity of lateral branches, which will fill the heads of the trees with weak ſhoots, whenever their branches are thus ſhortened; and many times the fruit is thereby cut off, which, on many ſorts of fruit-trees, is firſt produced at the extremity of their ſhoots.

It may, perhaps, ſeem ſtrange to ſome perſons, that we ſhould recommend the allowing ſo much diſtance to the trees in an orchard, becauſe a ſmall piece of ground will admit of very few trees, when planted in this method: but they will pleaſe to obſerve, that, when the trees are grown up, they will produce a great deal more fruit than twice the number when planted cloſe, and will be vaſtly better taſted; the trees, when placed at a large diſtance, being never ſo much in danger of blighting as in cloſe plantations, as hath been obſerved in Herefordſhire, the great country for orchards, where they find that when orchards are ſo planted or ſituated, that the air is pent up amongſt the trees, the vapours which ariſe from the damp of the ground, and the perſpiration of the trees, collect the heat of the ſun, and reflect it in ſteams ſo as to cauſe what they call a fire-blaſt, which is the moſt hurtful to their fruit; and this is moſt frequent where the orchards are open to the ſouth ſun.

But, as orchards ſhould never be planted, unleſs where large quantities of fruit are deſired, ſo it will be the ſame thing to allow twice or three times the quantity of ground; ſince there may be a crop of grain of any ſort upon the ſame place, as was before ſaid, ſo that there is no loſs of ground: and, for a family only, it is hardly worth while to plant an orchard; ſince a kitchen-garden well planted with eſpaliers will afford more fruit than can be eaten while good, eſpecially if the kitchen-garden be proportioned to the largeneſs of the family: and if cyder be required, there may be a large avenue of apple-trees extended croſs a neighbouring field, which will render it pleaſant, and produce a great quantity of fruit; or there may be ſome ſingle rows of trees planted to ſurround the fields, &c. which will fully anſwer the ſame purpoſe, and be leſs liable to the fire-blaſts before-mentioned.

BRITISH MUSEUM 15 JUN 61

THE

THE GARDENER'S KALENDAR.

JANUARY.

The Works of this Month in the KITCHEN-GARDEN.

JANUARY being generally ſeverely cold, there is leſs work to be done in the garden than in ſome of the ſucceeding months, when the weather is more kind and indulgent to all ſorts of vegetables.

The gardener is not, however, wholly idle during this inhoſpitable month, eſpecially with regard to raiſing early cucumbers and melons, for which preparations, if not made before, muſt be deferred no longer.

Cucumbers and Melons.

Let about a load of freſh horſe-dung, not too full of ſtraw, be provided. Add a ſmall quantity of ſea-coal aſhes to it, mix the whole well together, and throw it into a heap; after laying a few days to ferment, turn it over a ſecond time, laying it up again in a heap: if there be a conſiderable quantity of ſtraw in it, there will be a neceſſity for turning it over a third time after having lain a few days; this will rot the ſtraw, and mix it thoroughly with the dung, ſo that there will be the leſs danger of burning when the bed is made.

When the dung is thus prepared, mark out the foundation of your bed, in proportion to your light frame, which may very eaſily be done, by ſetting it on the place where you intend to make your bed; then mark the place where the corners touched the ground, remove the frame, and drive down a ſtake in each of the four marks, making an allowance for the bed to be two inches wider each way than the frame.

You ſhould remember that the place where the hot-bed is made, muſt be well ſheltered with reed hedges, and the ground very dry. A trench ſhould alſo be made in the ground of a proper length and breadth, and about a foot deep, into which let the dung be wheeled, and carefully ſtirred up and mixed; ſo that no part of it be left unſeparated; for where there is not this care taken, the bed will ſettle unequally. Care ſhould alſo be taken to beat the dung down cloſe with the back of your fork, in every part of the bed. Some tread the bed; but it will work much more kindly, if ſuffered to ſettle gradually of itſelf.

When the bed is finiſhed, the frame and glaſſes ſhould be put upon it to keep out the rain; but no earth ſhould be laid on the dung till two or three days after, that the ſteam of the dung may have time to evaporate. Let the glaſſes be kept cloſe till the heat riſes to the top, and then raiſe them properly, that the ſteam of the dung may paſs away. If there ſhould be any danger of the bed's burning, it will be proper to lay ſome old dung, or, what is ſtill better, cows dung, over the top of the hot dung, which will effectually keep down the heat, and prevent the earth from being burnt.

When the bed has been made four days, take off the frame and glaſs, and make it perfectly level and the ſurface ſmooth. Then put on the frame, and throw upon the dung as much dry earth as will cover it about two inches and a half thick. At the ſame time fill four or five ſmall pots with rich dry earth, place them on the bed, put on the glaſſes, and keep the whole cloſe till the earth in the pots is warm. As ſoon as this is effected, ſow a few cucumbers or melon ſeeds in each pot, covering the ſeeds about half an inch thick with the ſame earth as that in the pots. The ſeeds ſhould be at leaſt three or four years old. Place the pots in the middle of the bed, and draw ſome of the earth of the bed round each pot. Cover the glaſſes every night with a ſingle mat only for the three or four firſt nights after the ſeed is ſown; but the covering muſt be augmented, as the heat decreaſes.

As the bed is yet very warm, it will be neceſſary to examine it every day, that the pots have not too much heat, which you may eaſily prevent by raiſing the pots farther from the dung. And this is indeed the true reaſon why the ſeeds are ſown in pots, becauſe they can be conveniently raiſed, without giving the leaſt diſturbance to either the ſeeds or plants, and the injury ariſing from too much heat, eaſily prevented.

If proper care be taken, the plants will appear in three or four days after the ſeeds are ſown, when it will be proper to give them air, by raiſing the glaſſes a little every day; and if the earth in the pots appear dry, refreſh it moderately with a little water that has ſtood all night in the bed; but great caution muſt here be uſed; for though the cold muſt be taken off, yet if it be too warm it will deſtroy the plants. They muſt alſo be guarded from the moiſture that frequently drops from the glaſſes, for it will greatly injure them.

If you find that the heat of the bed is ſtrong, let the glaſs be raiſed a little with a prop, when you cover it in the evening; and if a mat be nailed to the frame, ſo as to hang down over the end of the glaſs that is raiſed, the plants will be ſufficiently guarded from the cold, and at the ſame time enjoy the advantage of the freſh air. But when the heat becomes more moderate, the glaſs

may be ſhut cloſe every night, obſerving to give the plants air in the day-time, and to hang a mat before the place, as already directed.

As theſe plants are very liable to ſuffer from various cauſes at this ſeaſon of the year, it will be very prudent to ſow a little more of the ſame ſeed in the ſame bed, and in the ſame manner as above directed. Nor would it be wrong to ſow a little ſeed at three different times in the ſame bed, that if one ſowing ſhould miſcarry, another may ſucceed.

When the plants have been up three or four days, they ſhould be planted into ſmall pots, and placed in the ſame bed; but you muſt remember to fill the pots the day before you intend to remove the plants, with rich dry earth, and ſet them within the frame till the next day, that the earth in the pots may acquire a proper degree of warmth. This being done, let about an inch deep of the earth be taken out of the pot; forming a ſmall hollow, like that which might be made by preſſing on it the head of a ſmall watering-pot, in the earth remaining in the pot, and lay the plants on the ſide of it, with their roots towards the center, and cover their ſhanks near an inch thick, with ſome of the earth that was taken out of the pots. Three or four cucumber plants may be thus placed in each pot; but two melon plants will be ſufficient for each pot.

When all the plants are thus ſet, let the pots be plunged into the earth in the bed, cloſe to one another, and all the ſpaces between them carefully filled up with earth. At the ſame time let the whole ſurface of the bed within the frame be covered with ſo much dry earth as will prevent the riſing of the ſteam from the dung, which would deſtroy the plants. There ſhould always be a magazine of good earth laid under cover to keep it dry, in order to earth theſe beds; for if it be taken up wet it will not only chill the bed, but alſo occaſion great damps in it: it is therefore neceſſary to have a ſufficient quantity of earth prepared long before it is uſed.

As ſoon as the plants are fairly rooted, which will be in two or three days after planting, let them be refreſhed with a little water in the warmeſt time of the day; if the ſun ſhines, it will be the better for the plants; but the water muſt have ſtood a ſufficient time within the frame before it is uſed: and as theſe waterings ſhould be repeated moderately, as often as the earth in the pots grows dry, it will be prudent to keep a quart bottle or two full of water within the frame, that it may be always of a proper warmth to be given to the plants whenever they require it.

As it is neceſſary to preſerve the heat of the bed, you ſhould lay ſome ſtraw, hay, or fern, round it, and as high as the earth within the frame, By this means neither rain nor ſnow will chill the bed, which would cauſe a ſudden decay of the heat, and, conſequently, greatly check the growth of the plants.

When you find the heat of the bed begins to decline, remove the ſtraw, hay, or fern, from the front and back of the bed, and apply a lining of freſh horſe-dung to both, raiſing it a little higher than the dung of the bed, and covering the top two inches thick with earth. This covering is abſolutely neceſſary to prevent the rank ſteam of the dung from entering the frame among the plants, where it would prove deſtructive.

This lining will ſoon revive the heat of the bed, and continue it near a fortnight longer. But you ſhould not wait till that heat ſubſides: about ten days after the firſt lining is finiſhed, take the ſtraw, hay, or fern, from the other two ſides of the bed, and lay there a lining of freſh dung, as before directed: this will again revive the heat; and the dry litter that was laid round the bed, may be now laid round the lining, which will at once protect it from the cold, and prevent, in a great meaſure, the heat from evaporating. By theſe precautions the heat of the bed may be preſerved for near a fortnight longer.

By proceeding in this manner with making new linings, the plants may be kept in a free growing ſtate in the ſame bed wherein the ſeed was ſown, till they are fit to be tranſplanted into the bed where they are to produce their fruit.

You ſhould obſerve to procure the hotteſt dung for linings, and to ſhake it up in a heap eight days before you uſe it; if in that time it be turned once over, it will be the fitter for the intended purpoſe.

Aſparagus.

In order to raiſe aſparagus on hot-beds, a piece of ground that has been made rich with dung, and well dug and mellowed, muſt be made choice of. Upon this ground ſtrike out lines ſeven or eight inches aſunder, and plant the aſparagus roots in them at four inches diſtance, when they are a year old: in this nurſery they are to remain two years, and be kept clean from weeds, before they are fit for the intended purpoſe. The hot-bed muſt be made pretty ſtrong, and covered immediately with earth ſix inches deep, encompaſſed about with bands of ſtraw. In this bed plant your aſparagus roots from the nurſery, as cloſe as they can be placed together without trimming them. This being done, cover the buds of the plants two inches thick with earth, and let them remain five or ſix days, without putting the frames and glaſſes over them; then lay three inches thick of earth over the whole, and put on the frames and glaſſes. In about ten days after planting the buds will appear: and then give them what air the ſeaſon will permit; for the more air they have, the greener, and better taſted they will be. The bed will laſt about a month, producing freſh buds daily, if the weather be not too ſevere. When the heat of the bed begins to decline, warm horſe-litter laid upon the glaſſes every night will contribute as much to facilitate the ſhoot of the buds, as if new dung were applied to the roots.

Raddiſhes.

Raddiſhes are ſown on a hot-bed having a ſufficient thickneſs of good rich light mould, that they may have depth to root in before they reach the dung. And to have large and clean raddiſhes, make holes as deep as your finger, about three inches diſtance; drop into each hole a ſound ſeed or two, and cover the ſeeds a little, leaving the reſt of the hole open; by which means they will grow to the height of the hole before they dilate their leaves, and leave a long and tranſparent root.

There are ſeveral varieties of raddiſhes; as the ſmall-topped, the deep-red, the pale-red, or ſalmon, and the long-topped ſtriped raddiſh. The ſmall-topped is moſt commonly preferred by the gardeners near London, becauſe

cauſe they require much leſs room than thoſe which have large tops.

If the weather be open at the beginning of this month, you ſhould ſow ſome ſmall-topped and ſalmon-raddiſhes on a warm border, fully expoſed to the ſun, and defended from the north winds by a wall or other cloſe fence.

You muſt however be very careful not to mix the ſeeds: each ſort ſhould be ſown by itſelf; for the ſmall-topped will be fit to draw a full week at leaſt before the other, though both are ſown at the ſame time, and on the ſame bed. There is alſo another reaſon, viz. the latter runs more to leaves than the former. They ſhould therefore have more room to ſpread, for otherwiſe their roots will be very ſmall.

Both ſorts ſhould be ſown pretty thick at this ſeaſon; becauſe the birds will pick up all they can find, and, if not prevented, deſtroy the whole. The weather alſo will deſtroy ſome; ſo that unleſs great care be taken, and a conſiderable quantity of ſeed ſown at firſt, very few plants will come to perfection. Means ſhould therefore be uſed to keep off the birds; and if the weather ſhould prove froſty after the plants are up, a little ſtraw or dry fern, ſhook lightly over the bed, will be of great ſervice to the tender plants; nor will they be bruiſed by this covering, provided care be taken in laying it on, and taking it off the bed.

You will do well to ſow a little of the ſame ſeed at leaſt twice in the month, in the beginning and towards the latter end; by which means you will have a continual ſupply of raddiſhes, till the natural crop comes in.

Some ſow their ſeed on a warm ſpot in the common ground, covering it with a frame and glaſſes; by which means they procure a crop at a very acceptable ſeaſon, and have often the pleaſure of ſeeing this bed produce a better return than that ſown on a hot-bed.

Lettuce.

You may alſo raiſe lettuce-plants under a frame with glaſſes, at this ſeaſon of the year; but you muſt be careful to let them enjoy the benefit of the open air as often as poſſible; not by lifting up one of the ends of the glaſſes, but by taking them entirely off the frame, when the weather is dry and mild; but when it is wet, the glaſſes muſt be kept upon the frames, though raiſed to a very conſiderable height, that the air may have free admiſſion to the plants. When the weather is ſevere, they muſt be kept cloſe night and day; and the glaſſes covered every night, and even in the day-time if no ſun appears, and the wind be very ſharp, with mats, or ſtraw.

You muſt be careful to pick off all the dead leaves as they appear upon the plants; and ſtir the ſurface of the ground between them often, taking away all the weeds, or other litter, which would otherwiſe greatly injure their growth.

You may ſow ſome coſs, cabbage, or brown Dutch lettuce, about the middle of this month, on a warm border, under a wall or pales; obſerving, when you dig the border, to lay it a little ſloping to the ſun. If the weather ſhould prove ſevere ſoon after the ſeed is ſown, it will be adviſeable to ſow a little more about the latter end of the month, in order to ſecure a forward crop of lettuce, leſt the ſeed ſown firſt ſhould be deſtroyed.

Small Salleting.

As the weather is generally too ſevere this month for ſowing creſſes, muſtard, rape, &c. in the open air, a ſlight hot-bed ſhould be made, on which the ſeeds are to be ſown. Eighteen or twenty inches deep of dung will be ſufficient for the purpoſe; and if you are in want of frames and glaſſes, hoops fixed acroſs and covered with mats will anſwer the intention. The bed muſt be covered five or ſix inches thick with light dry mould. In this mould let ſhallow drills be drawn from the back to the front of the bed, and the ſeed of each ſort ſown pretty thick in theſe drills, covering it about a quarter of an inch deep with mould. But be ſure to give the plants air as ſoon as they appear, by raiſing the glaſſes or mats; for otherwiſe they will mould and ſpoil, as faſt as they come up; ſo very neceſſary is the freſh air to the growth of theſe tender plants.

You may make a bed to raiſe a ſallet in a few hours by the help of powdered lime and hot dung. A layer of the lime muſt be laid firſt, then one of dung, and over that another of lime: the laſt muſt be covered with fine rich mould, and the ſeed ſown upon it, in the uſual manner, covering it very ſlightly.

But if you cannot conveniently make a hot-bed of any kind, you may, if the weather be favourable, ſow the ſeed on a warm border under or near a ſouth wall; obſerving to lay the border ſloping towards the ſun, raiſing it about a foot higher on the north than on the ſouth ſide. Sow the ſeeds on this bed, and put on the frame and glaſſes. The ſucceſs will be certain, unleſs the weather prove very ſevere, when a hot-bed will be abſolutely neceſſary to ſupply the warmth neceſſary to the vegetation of theſe plants.

Cauliflowers.

Pick off all the leaves that are either withered or damaged from your cauliflower-plants, and ſuffer no weeds to grow among them. It will alſo be of great uſe if you can conveniently ſtir the ſurface of the ground about the plants. But however that be, let them have plenty of air every day, by either raiſing the glaſſes, or taking them entirely off the frame, when the weather is mild and dry; but do not open them at all in froſty weather.

You ſhould alſo in ſevere weather remember to cover the glaſſes every night, and ſometimes even in the day-time, with mats, ſtraw, or fern. A little litter laid on the outſide of the frame will likewiſe be of uſe, eſpecially if the joints of it be not very cloſe, as this method will prevent the froſt from affecting the plants.

If your plants are covered with hand or bell-glaſſes, they muſt have air given them every day by raiſing the glaſſes on the ſide next the ſun; but in ſharp weather the glaſſes, muſt be kept cloſe; and in ſevere weather long litter ſhould be laid round each glaſs, which will greatly protect the plants from the injuries of the ſeaſon. Every mild dry day the glaſſes may be taken off the plants for four or five hours; but they muſt be kept cloſe every night; a little earth ſhould alſo be drawn up round the ſtem of the plants.

Cabbages.

Cabbages.

Let a convenient ſpot of ground be prepared, when the weather is open, for cabbage plants. The manner of preparing it is this: Lay a ſufficient quantity of rotten dung upon the ground, and dig it a ſpade deep, burying the dung at the bottom of the trench. Into this ſpot the plants may be removed about the latter end of this month, planting them about a foot and a half aſunder. Any of the larger ſorts of cabbages may be planted at this ſeaſon; but the ſugar-loaf and early Yorkſhire cabbage are the moſt proper.

In the other beds, where any of the plants have been deſtroyed either by vermin or the ſeverity of the weather, let their places be new ſupplied with others.

If you ſhould have neglected to tranſplant cabbages for ſeed in the months of November and December, that work may ſtill be done, provided the weather be dry and open. The manner of doing it is this:

Make choice of ſome of your beſt cabbages, pull them up, and carry them to ſome ſhed, or covered place, and there hang them up by their ſtalks, for four or five days, that all the water may drain away from between their leaves; then plant them in ſome border under a hedge or pale, quite down to the middle of the cabbage, leaving only the upper part of it above the ground, obſerving to raiſe the earth about it, ſo that it may ſtand a little above the level of the ground; eſpecially if the ſoil be wet, for then it will be neceſſary to raiſe them conſiderably above the ſurface.

If the weather ſhould prove very ſevere, you muſt lay a little ſtraw, peaſe-haulm, or fern, lightly over them to ſecure them from the froſt, taking it off whenever the weather proves mild, leſt by keeping them too cloſe they ſhould rot. Theſe cabbages will, by this management, ſhoot out ſtrongly in the ſpring, and divide into a number of ſmall branches.

Mint.

A ſmall hot-bed ſhould be made this month for mint, that will be fit for uſe early in the ſpring. About nine inches deep of dung will be ſufficient for the purpoſe. This ſhould be covered with earth five or ſix inches thick, upon which the roots of mint are to be placed, and covered with earth about an inch and a half deep. Let the bed be covered with a frame and glaſſes, or in want thereof with mats ſupported by hoops fixed acroſs the bed.

Parſley.

If the weather be open, ſome parſley ſeed may be ſown about the middle or latter end of the month, in a warm part of the garden. The drills ſhould be ſhallow, the ſeed ſown in them tolerably thick, and covered with earth about an inch and a quarter deep.

Moſt gardeners ſow parſley in a ſingle drill along the edges of the borders near the paths, where it will flouriſh without taking up too much room.

Beans.

A great variety of garden-beans are now cultivated in the kitchen-gardens of England, differing both in ſize and ſhape; ſome of them producing their pods much earlier in the year than others, for which they are greatly eſteemed.

The Magazan bean is the firſt and beſt ſort of early beans at preſent known; theſe are brought from a Portugueſe ſettlement of the ſame name on the coaſt of Africa, juſt without the Straits of Gibraltar; the ſeeds of this ſort are much ſmaller than thoſe of the horſe bean; and as the Portugueſe are but ſlovenly gardeners, there are commonly a great number of bad ſeeds among them.

The next ſort is the early Portugal bean, which appears to be the Magazan ſort ſaved in Portugal; for it is extremely like thoſe ſaved the firſt year in England. This is the ſort generally uſed by gardeners for their firſt crop; but theſe are not near ſo well taſted as the Mazagan: when therefore the latter can be procured, no perſon of ſkill would plant the former.

The ſmall Spaniſh bean comes next; this will ripen ſoon after the Portugal ſort; and being a ſweeter bean, ſhould be preferred to it.

Soon after the Spaniſh comes the Sandwich bean; this is almoſt as large as the Windſor bean, but being hardier is commonly ſown a month ſooner; it is alſo a very plentiful bearer.

The Toker bean, as it is generally called, comes about the ſame time with the Sandwich, and being a great bearer, is often planted.

Both the white and the black bloſſom beans are alſo by ſome perſons much eſteemed: the beans of the former are, when boiled, almoſt as green as peas; and this property added to their being very ſweet, renders them valuable; but both theſe ſorts are very apt to degenerate, if their ſeeds are not ſaved with great care.

The Windſor bean is allowed to be the beſt of all the ſorts for the table; when theſe are planted on a good ſoil, and allowed ſufficient room, their pods will be very large, and in great plenty. They are alſo, when gathered young, the ſweeteſt and beſt taſted of all the ſorts: but great care ſhould be uſed in ſaving the ſeed, by pulling up ſuch of the plants as are not perfectly right, and afterwards by ſeparating all the good beans from the bad, when they are taken out of the pods.

If the weather be mild at the beginning of this month, let a proper ſpot of ground be prepared for a principal crop of Sandwich beans. They may, if the weather permits, be planted the firſt week in this month. The rows ſhould be ſix feet diſtance from one another, and the beans ſet five or ſix inches aſunder in the rows.

A few Windſor beans may alſo be planted about the ſame time; but it will be more adviſeable to defer the main crop till near the latter end of the month, for they are leſs hardy than the Sandwich bean. The rows ſhould be a yard aſunder, and the beans planted full ſix inches apart. The diſtance between the beans and the rows, is, by ſome gardeners, thought too great; but Mr. Miller aſſures us, he has found from many years experience, that the ſame ſpace of ground will produce a greater quantity of beans, when planted at the above diſtance, than if double the quantity of ſeeds were ſet in it.

The ſame ingenious gentleman alſo obſerves, that a very bad cuſtom too often prevails in gentlemen's kitchen-gardens, namely, that of planting beans for an early

early crop close to the garden-walls, on the best aspects, immediately before the fruit-trees; which is certainly of greater prejudice to the trees, than the value of the beans, or, indeed, of any other early crop: this practice therefore should be every-where discouraged; for it is much better to run some reed hedges across the quarters of the kitchen-garden, where early beans and peas may be planted, where they may more conveniently be covered from the frost, and to which they may be more easily fastened as they advance in their growth, than to walls, covered with good fruit-trees, which must be greatly prejudiced by such practice.

Peas.

There are a great variety of garden-peas now cultivated in England, and which have different titles given them by the gardeners and seedsmen; but as great part of these have been seminal variations, so if they are not very carefully managed, by taking away all those plants which have a tendency to alter, before the seeds are formed, they will again degenerate into their original state. Those persons therefore who are desirous of preserving any variety of peas, should look carefully over those plants they design for seed, at the time they begin to flower, and draw up all the plants they dislike. This is what the gardeners call rogueing their peas; signifying thereby, the separating all the bad plants from the good, that the farina of the former may not impregnate the latter; to prevent which they always do it before the flowers open: by this judicious practice, and by preserving those for seed which flower soonest, they have, of late years, greatly improved their peas, and are constantly endeavouring to procure still forwarder varieties; so that it would be of very little use, should one attempt to give an account of all the varieties now cultivated; it will therefore be sufficient to mention only the titles by which they are generally known, placing them according to the time of their being fit for the table.

The golden hotspur.	Nonpareil.
The Charlton.	Sugar-dwarf.
The Reading hotspur.	Sickle pea.
Masters's hotspur.	Marrowfat.
Essex hot-spur.	Rose, or crown pea.
The dwarf-pea.	Rouncival pea.
The sugar-pea.	Gray pea.
Spanish Morotto.	Pig pea.

Some golden hotspurs may be sown the beginning of this month, for a full crop, on a warm piece of ground: let them be sown in rows a yard distance. This crop will succeed that sown in December.

You may also sow at the same time, the first crop of marrow-fat peas; and they will succeed the hotspurs; for they will begin bearing as the others give over. This pea is greatly admired in most families; but the dwarf marrowfat is the most proper to be sown at this season.

If you intend to set sticks in the ground for these peas to run up, the rows must be at least four feet from one another; but if no sticks are intended, three feet and a half will be fully sufficient.

Those beans and peas, if any, already up, should, when the ground is dry, and the weather mild, have some earth drawn up to their stems; for this will at once strengthen the plants, and be of great service in protecting them from the frost.

Celery.

Earth up the celery that requires it, on a dry day, when the weather is open. Take care that the earth be well broken, and laid lightly to the plants, that they may neither be crushed down, nor their hearts buried.

Let the earth be raised very near the top of the plants; for should severe frosts set in, all the plants of the celery above the ground will be destroyed; and if any considerable part of the plants should be destroyed, it would even occasion a decay in those parts which are under the surface.

In some families these plants are required every day; some of the rows should therefore be covered with light dry litter, on the approach of hard weather, otherwise it will be impossible to take them up. This method will at once prevent the ground from being frozen, and protect the plants from the piercing coldness of the weather.

Endive.

At this season some of the endive planted about September or October should, when the weather is mild and dry, be taken up, and laid in a ridge of dry earth to blanch. But be sure to hang the best and largest plants a day or two in a dry place, before they are laid in the earth, that the moisture lodged between their leaves may drain off, otherwise the heart of the plants will be rotten before the blanching is completed.

Let the ridge intended for the reception of these plants be prepared in the driest part of the garden, and where the ground is light and fine. The trench should be about two feet and a half wide, and sideways to the mid-day sun. Let it be a good spade deep, and the earth be laid on the north side of the trench, close to the edge, forming a high ridge. Make the sunny side, or that next the trench, as upright as possible, in order to drain off the heavy rains; for if water lies about the plants, it will destroy them.

When your ridge is thus prepared, gather the leaves of each plant regularly and close in your hand, make an opening on the sunny side of the ridge, and put the plant sideways into the earth, almost to the tops of the leaves. The plants may be laid pretty near to each other, so that a short trench will be sufficient for a considerable number.

But there is still a surer method of blanching endive at this season; namely, by laying some dry earth, or old tan, in a frame, sloping to the sun; and burying your endive plants therein almost to the tops of the leaves. When the weather is either wet or frosty, the glasses and other covering, if you think it necessary, may be put on: and by this method there will be no danger of obtaining excellent endive in the severest season; provided care be taken to lay down a quantity at the beginning of a hard frost. A single frame will hold a very considerable number of plants, as they may be laid almost close to each other.

Carrots.

At any time of the month, when the weather will permit, a warm spot of ground should be prepared for a few

few early carrots. Let the earth be dug a full ſpade deep, and the mould broken very fine as you proceed. A ſmall ſpot will be ſufficient for the purpoſe, as it is only intended to raiſe a few that may be fit for the table before the general crop. Let the ſeed be ſown when the weather is mild, and raked in as ſoon as ſown.

If you make uſe of a hot-bed for raiſing carrots early, the earth ſhould be at leaſt ſix inches thick. If you have no frame at liberty, let the bed be arched over with hoops, and covered occaſionally with mats.

Spinnage.

If you are deſirous of having ſpinnage early in the ſpring, a little ſeed may be ſown in a warm ſpot, about the beginning of the month, and a little more towards the latter end, in order to obtain a regular ſucceſſion. The ſmooth-ſeeded, or round-leaved ſpinnage is the beſt to ſow at this ſeaſon.

Muſhrooms.

Your muſhroom-beds will require conſiderable attendance this month. The plants muſt have a covering ſufficient to defend them from the froſt, rain, or ſnow; and if, by accident, the rain ſhould have penetrated quite through the covering, it muſt be renewed immediately, or your ſpawn will be in danger of periſhing. Let it therefore be replaced with a good covering of wheat or other ſtraw; and if the wet weather be likely to continue, it will not be amiſs to lay ſome mats, or other covering over the ſtraw; for this will greatly tend to preſerve the beds from injury.

The FRUIT-GARDEN and ORCHARD.

Vines.

In pruning vines, which may be done any time this month, obſerve to take away the leſſer and weaker ſhoots, which bear any fruit, and to leave a ſufficient number of the other branches to furniſh every part of the wall, without confuſion.

The ſhoots ſhould be ſhortened to four or five eyes in length; let the branches be cut off about half an inch above an eye, and in a direct ſloping from it; and the branches nailed as ſoon as they are pruned, at about 12 or 13 inches from one another.

You ſhould obſerve to leave every year ſome ſhoots near the bottom of the wall, that you may have a conſtant ſucceſſion of young wood coming up in regular order, in order to ſupply the place of ſome of the old and moſt unſerviceable part of the wood, which ſhould be cut away, when it has advanced near the top of the wall, as it will be then in a manner uſeleſs. This uſeleſs part ſhould be cut away near the bottom, or ſome convenient young branch growing from it, leaving the latter to ſupply the place of the former.

All ſorts of vines are propagated either from layers, or cuttings, the former of which is generally practiſed in England; but the latter recommended by Mr. Miller, is much preferable to the other. He very juſtly obſerves, that the roots of vines do not, like moſt other ſorts of trees, grow ſtrong and woody, but long, ſlender and pliable; and for this reaſon, when they are once taken out of the ground, they ſeldom ſtrike out any fibres from the weak roots, which generally ſhrivel and dry; ſo that they rather retard than help the plants in their growth, by preventing the new fibres from puſhing out: it will be therefore better to ſet a good cutting, provided it be well choſen, than a rooted plant, as there is very little danger of its growing.

But as there are few perſons who make uſe of proper cuttings, or at leaſt that rightly form their cuttings in England, a few directions for that purpoſe will be neceſſary. You ſhould always make choice of ſuch ſhoots as are ſtrong and well ripened, of the laſt year's growth; theſe ſhould be cut from the old vine, juſt above the place where they were produced, taking a knot, or piece, of the two-years wood, to each, which ſhould be pruned ſmooth; you ſhould then cut off the upper part of the ſhoots, ſo as to leave the cutting about ſixteen inches long. When the piece, or knot, of old wood is cut at both ends, near the young ſhoot, the cutting will reſemble a little mallet; whence Columella calls it Malleolus. In making the cuttings after this manner, there can be only one taken from each ſhoot; whereas moſt perſons cut them into lengths of about a foot, and plant them all: but this is very wrong: for the upper part of the ſhoots are never ſo well ripened as the lower, which was produced early in the ſpring, and had the whole ſummer to harden; ſo that if they take root, they never make ſo good plants; for the wood of thoſe cuttings being ſpungy and ſoft, admits the moiſture too freely, whereby the plant will be luxuriant in growth, but never ſo fruitful as that whoſe wood is cloſer and more compact.

When the cuttings are thus prepared, they ſhould be planted immediately, or placed with their lower parts in the ground of a dry ſoil, laying ſome litter on their upper parts to prevent them from drying: in this ſituation they may remain till the beginning of April, when they ſhould be taken out of the ground, and waſhed from the filth they have contracted; and if you find them very dry, let them ſtand with their lower parts in water ſix or eight hours, which will diſpoſe them for taking root. The ground being properly prepared, open the holes at about ſix feet diſtance from each other, and put one good ſtrong cutting in each hole, laying them a little ſloping, that their tops may incline to the wall; but they muſt be put in ſo deep that the uppermoſt eye may be juſt level with the ſurface of the ground; for when any part of the cutting is left above ground, as is the common method uſed by the Engliſh gardeners, moſt of the buds attempt to ſhoot; ſo that the ſtrength of the cutting is divided to nouriſh ſo many ſhoots, which muſt conſequently be weaker than if only one of them grew; whereas, on the contrary, by burying the whole cutting in the ground, the ſap is all employed on one ſingle ſhoot, which muſt, conſequently, be much ſtronger: beſides, the ſun and air are apt to dry that part of the cutting which remains above ground, and by that means often prevents its buds from ſhooting.

Apples, Pears, &c.

If any of your wall or eſpalier trees ſtill remain unpruned, let the work be forwarded now as much as poſſible.

possible. When old pear-trees are vigorous, and the space of the wall assigned for each is not sufficient to contain their branches, when properly extended, take away every second or third tree, according as room is wanted, before you prune them. And if the old branches are placed horizontally, lay the new ones left in the middle of the tree in that position between them; but if the old horizontals are too near one another, and the tree not vigorous, part of them may be cut away to make room for the new ones; together with such branches as would shade the young horizontals. There should be nothing left in these places but what will blossom that year; nor should there be too many buds left for that purpose.

If the tree be weak, it should be considerably thinned, by taking out part of the bearers. You may easily know what buds will produce blossoms by their shapes; they are more globular than others; and these only should be left on those parts of the old horizontals which are nearest the stem, where the young horizontals are interlaid; but let all the collaterals that are not too long for bearers, and near the extremities of the tree, remain.

Every branch, &c. taken from a tree, must be cut off close to the part from whence it proceeded; for when stumps are left, they are apt to produce a number of useless branches.

The hardier sort of apples require much the same management in pruning. Some kinds of apples, especially the nonpareil, will sometimes bear a small number of fruit upon young wood, or shoots of the last year's production; but they generally bear most upon studs, or spurs, proceeding from branches of two, three, or four years old.

When any of the horizontals are cankered, take off the rind as far as the quick, and let all the moss be clean scraped off, both from them and the stem; which may best be done in wet weather; but if the weather be dry, moisten the trees well with brine, and when the moss is taken off, wash them again with the same liquor, which will prevent moss from growing upon them for the future; by this means the eggs of caterpillars concealed in the cavities of the old bark, will be, in a great measure, destroyed.

With regard to the pruning orchard trees, nothing more should be done than to cut out all those branches that cross each other, which if left would rub and tear off its own bark, together with that of the branches it crosses: all decayed branches should likewise be taken away; and when any branches are broken by the wind, they should be cut off, either down to the division of the branch, or close to the stem from whence it was produced. But this work should never be done in frosty weather.

Plums and Cherries.

Though these trees are somewhat tenderer than the apple and pear-trees, yet if the weather be not severe, they may be safely pruned and nailed, either against walls or espaliers.

Cherries of different kinds require different ways of pruning and nailing, because they bear their fruit on wood of different ages; the morello and baremdam bear most of their best fruit upon the extremities of the last year's shoots, and should therefore be cut and nailed every year, so as to procure a succession of them. With regard to the other sorts of cherries, let it be observed, that all such young shoots of the last year's growth, as are now intended to furnish the wall or espalier with bearing wood, must not be shortened; but every such shoot or branch must be left at its full length; and this should at all times be practised, which is the only way to render the branches fruitful; for the shoots thus treated will in two years time, send out many shoots, or fruit-spurs, about half an inch or an inch in length, and from these spurs the fruit is always produced. These spurs generally appear first near the extreme part of the branches; so that by shortening them, that part where the blossom-buds would otherwise have made their appearance, would consequently be cut away.

In nailing these, or indeed any other kind of stone fruit, take care that the rind be neither galled nor bruised by either hammer or nail; for this will cause gum to issue from the wounded part, which will either kill or weaken the part it proceeds from.

Plum-trees are observed to produce the best fruit upon the youngest bearers, unless too great a number of them be suffered to remain; these should therefore be carefully preserved; by which means a large quantity of the best fruit will be procured.

We have already observed, that the top or young shoots left for bearing wood, should not be shortened in either apples, pears, or cherries; and shall now add, that the same should be observed with regard to plums. But in some instances this useful rule must be dispensed with; particularly when the trees are about six years old from the budding or grafting, and newly planted against walls or espaliers. For it is necessary that all the shoots produced the two first years after the budding or grafting, should be shortened; which should be done in the spring, cutting them to four or five eyes; by which means they will put out lateral branches near the ground, and furnish regularly the wall or espalier with branches from the bottom. After this the branches are to be trained along at their full length, except it should be found necessary to shorten one or two of the middlemost shoots, in order that each may throw out two or three lateral branches, to furnish that part of the tree. Let these lateral shoots also be trained at their full length, unless there are still more branches wanting, when one or two of the most convenient of the last shoots may be likewise shortened, to promote their producing more lateral branches, to cover the wall: for the great art consists in encouraging young fruit-trees to produce shoots in proper places, so as to cover the wall or espalier regularly with branches, from the bottom to the top.

But when the trees have acquired branches sufficient to cover the wall or espalier in regular order, you are then to shorten no more of the branches, except in cases where wood is wanting.

Peaches, Apricots, and Nectarines.

If the weather proves mild, peaches, apricots, and nectarines, may be pruned and nailed any time this month. For though they are rather more tender than any of the sorts above mentioned; yet extreme hard frost only can affect the parts that are newly cut; and in such severe weather no pruning should be attempted.

There is very little difference in the method necessary to be observed in pruning either of these trees; the fruit

of them all being produced from the ſhoots of the laſt year; a proper ſupply therefore of the beſt of the laſt year's ſhoots muſt now be left in a regular manner in every part of the tree; and theſe ſhoots muſt be ſhortened, in order to encourage them to produce a ſucceſſion of bearing wood during the ſucceeding ſummer; for the wood then produced will bear fruit the ſummer after.

It will be proper, before you begin pruning, to unnail the greater part of the tree, that room may not be wanting to uſe your knife properly; and when you have finiſhed the pruning of one tree, let that be nailed up again, before you proceed to another.

But be careful to remember, in the pruning of theſe trees, to ſelect the moſt promiſing and beſt ſituated ſhoots, which are to be preſerved at proper diſtances in every part of the tree, and room made for them by cutting away the decayed ſhoots, and old uſeleſs wood.

Another circumſtance neceſſary to be remembered is, that the ſhoots ſhould always be ſhortened in proportion to their own ſtrength and that of the tree. If the latter be weak, the ſhoots ſhould be left about ſix or ſeven inches from one another, and ſhortened according to their ſtrength: ſome may be left ſix, others eight, ten or twelve inches long; varying the length of the ſhoot in proportion to its ſtrength.

If the tree be neither very vigorous nor very weak, the ſhoots ſhould be laid in about five or ſix inches aſunder, and ſhortened to about eight, ten, twelve, or fifteen, in proportion to their ſtrength.

But where the tree is very vigorous, the ſhoots ſhould be very little ſhortened; ſome to the length of ten, twelve, or fifteen inches, whilſt the ſtrongeſt may be laid in eighteen inches, or two feet long, and ſome of them even at full length.

Care ſhould be taken, in ſhortening the ſhoots of theſe trees, to cut them off, if poſſible, at an eye likely to produce a leading ſhoot: ſuch eyes are known by their having two bloſſom-buds; between which there will iſſue a wood, neceſſary to the welfare of the fruit; for where ſuch a ſhoot is produced at the extremity of a bearing branch, it draws nouriſhment to the fruit, and renders it much finer than the fruit of thoſe ſhoots deſtitute of leaders.

Gooſeberry and Currant-trees.

It is a common practice in pruning gooſeberry-ſhrubs, to make uſe of garden ſheers, obſerving only to cut the head round, as is practiſed for ever-greens, &c. whereby the branches become ſo much crowded, that what fruit is produced, never grows to half the ſize it would do, were the branches thinned and pruned according to art; which ſhould always be done with a pruning-knife, ſhortening the ſtrong ſhoots to about ten inches, and cutting out all thoſe which grow irregular, thinning the fruit-bearing branches where they are too cloſe, obſerving always to cut behind a leaf bud. With this management the fruit will be near twice as large as thoſe produced upon ſuch buſhes as are not thus pruned, and the ſhrubs will continue much longer in vigour.

The currant-tree produces its fruit from the former year's wood, and alſo upon ſmall ſnags which come out of the old wood; ſo that in pruning this ſhrub, the ſnags ſhould be preſerved, and the young ſhoots ſhortened in proportion to their ſtrength. The only care neceſſary in pruning them is not to leave their ſhoots too cloſe, and never to prune their ſnags in order to make them ſmooth. This, with a ſmall degree of attention in obſerving the manner of their growth, will be ſufficient to inſtruct any perſon how to manage this plant, ſo as to produce great quantities of fruit.

You may during this month, provided the weather be mild, plant both gooſeberries and currants; and if the trees are to be ſet round the quarters of the kitchen-garden, prune them up to one ſtem, twelve or fifteen inches before you form the head of the tree; for when theſe trees are ſuffered to branch away immediately from their roots, they injure all the ſmall crops that grow near them, and render it very troubleſome to dig round them.

Raſpberries.

The method to be obſerved in pruning theſe plants, is to cut away the dead wood cloſe to the ground, clearing away all the ſmall ſhoots in general, and leaving only three or four of the ſtrongeſt ſhoots of the laſt ſummer's growth to bear fruit next year, upon each root. All the reſt ſhould be cut off cloſe to the ſurface of the ground.

At the ſame time thoſe ſhoots left for bearing, ſhould each of them be ſhortened, about one third, or at leaſt one fourth, of the length of each ſhoot.

The ſpaces between the rows ſhould be well dug to encourage their roots; and if you bury a little rotten dung therein, it will make them ſhoot vigorouſly the following ſummer, and their fruit will be much larger and better.

You may now make plantations of raſpberries, leaving at leaſt four feet between the rows, and ſetting the plants a yard diſtant in the rows. Theſe plantations are generally made with ſuckers; but Mr. Miller prefers ſuch plants as are raiſed by layers, becauſe they will be better rooted, and at the ſame time leſs liable than the others to ſend out ſuckers: and where theſe are not carefully taken off or thinned, the fruit will be ſmall and in little quantity, eſpecially when the plants are placed near each other, which is too often the caſe, few perſons being willing to allow theſe plants ſufficient room.

The PLEASURE or FLOWER-GARDEN.

Unleſs the utmoſt care be taken to protect your choiceſt flowers from the inclemency of the ſeaſon, they will ſuffer greatly; attention is therefore neceſſary for them all, though they in general require a different management.

Carnations, Hyacinths, &c.

Let your carnations that are in pots be well ſecured from froſt, heavy rains, and ſnow, which would greatly injure, if not intirely deſtroy them.

The beſt method is to plunge the pots at the beginning of winter into a bed of dry compoſt, arched over with hoops, which, when the weather is very wet or froſty, ſhould be carefully covered with mats. But when the weather is mild, let the covering be removed, that the plants may enjoy the free air, ſo neceſſary to their health.

You

You ſhould alſo in froſty weather cover the beds where you have depoſited the choiceſt kinds of hyacinths, tulips, or any other curious roots. Fern or long litter will do very well for this purpoſe: but you muſt remember to remove it, as ſoon as the ſevere weather is over.

As ſoon as any of the above plants begin to appear above ground, let the bed be arched over with hoops, and when the weather is either very wet or froſty, let them be covered with mats, faſtened down at the ſides to prevent the wind from blowing them off. But be ſure to take away the mats as ſoon as the weather is dry and open.

Auriculas.

As heavy rains, ſnow, or ſharp froſts, will greatly injure theſe delicate plants, they ſhould always be removed about the end of October into frames, or on a bed arched over with hoops, and ſituated in a warm place, where they may be conſtantly covered when the weather is unfavourable: but remember to take off the covering, whenever the weather is mild and dry.

About the latter end of the month, if the weather be mild, take away the upper part of the earth in the pots, as low as you can without diſturbing the roots, and fill up the pots with freſh rich earth, which will greatly ſtrengthen their bloom. The beſt compoſt for this purpoſe is good freſh light ſandy mould, mixed with very rotten neats dung, or any rotten dung from the bottom of an old hot-bed. At the ſame time clear the plants from all dead leaves. As ſoon as this is done, and the pots filled up with freſh mould, let them be returned to the place intended for ſheltering them from the weather.

Anemonies, Ranunculuſes, &c.

You may now plant thoſe roots of anemonies and ranunculuſes, &c. you reſerved, in order to ſucceed thoſe planted in October and November. But you muſt chuſe a mild day for this work, and take care that the ground be not very wet, which will rot the roots. Let the beds be laid arching, that the rain may run off: they ſhould not be more than four feet wide. In theſe the roots ſhould be planted in rows nine inches diſtant, and about ſix inches between each root. They ſhould be ſet about two inches and a half deep in the earth.

Tulips.

A few tulips may now be planted to ſucceed thoſe ſet in autumn. They ſhould not be deferred any longer, and therefore the firſt mild day ſhould be choſen for this pupoſe; for if they are not planted this month, they will blow but very poorly.

If they are to be planted in beds, let them be made rounding, that the wet may not remain on the ſurface, and about four feet wide. The roots ſhould be planted in rows about nine inches diſtant, and the ſame diſtance ſhould be allowed between the roots, which ſhould be ſet about four or five inches deep in the ſoil. If you plant ſome of the inferior roots in the borders, they may be ſet in a row about a foot from the edge, and the roots about the ſame diſtance from each other.

But if you plant them in little clumps, they will make a more beautiful appearance. For inſtance, if you plant four or five roots in a circle about eleven inches in diameter, with another in the center; and about ten or twelve feet further ſuch another clump, and ſo on to the end of the border; the effect, when the plants are in flower, will be very agreeable.

Crocuſſes.

Theſe ſhould be planted in borders by the ſides of the walks, within ſix inches of the edge of the border; but not in one continued row; for they appear to much greater advantage when planted in clumps, as was before obſerved of tulips. Obſerve alſo, if you have different kinds of crocuſſes, to plant each ſort ſeparate; that is, let one of the clumps be of the yellow ſort, the next of blue, and ſo on to the end of the border.

Jonquils, Narciſſuſes, &c.

If you have any left of theſe, or any other kind of bulbous roots, they ſhould be planted as ſoon as the weather will permit. Mild dry weather muſt be choſen to plant theſe, and indeed all other kind of flower roots. Nor ſhould the ground be too wet, for that will rot the roots.

Theſe, or any other ſpecies of bulbous roots intended to be ſet in the borders, ſhould be planted in clumps or patches, as we before directed for tulips, &c.

Double Sweet-Williams, double Wall-flowers, &c.

All the ſpecies of theſe flowers preſerved in pots, ſhould be carefully ſecured from ſevere froſt. If the plants are placed in frames, or beds arched over with hoops, let the glaſſes or mats be kept over them whenever the froſt is ſharp, and alſo in very wet weather. But the glaſſes or covering muſt be taken away in mild, dry weather; for a free circulation of air is of the utmoſt importance to their health.

Care ſhould alſo be taken to protect all the fibrous-rooted perennial plants in general, that are in pots, from the froſt. The pots ſhould be plunged to the rims in a dry warm border, and covered during the bad weather with long litter: at leaſt the pots ſhould be removed into ſome ſheltered place, at the approach of ſevere froſt.

Seedling-flowers.

Be very careful to lay peas-haulm, or fern, over your boxes of ſeedling-flowers in froſty weather; let the covering be of a conſiderable thickneſs, and preſſed cloſe down at the edges.

If your ſeedling-flowers are planted in beds in the garden, they ſhould likewiſe be covered with peas-haulm, fern, or long litter, during the froſt: but be ſure to remove it both from the beds and boxes, as ſoon as the weather is mild and open, that the tender plants may enjoy the benefit of a free circulation of air,

Flowering-ſhrubs.

All the flowering-ſhrubs planted in clumps in the ſhrubbery, ſhould now be pruned, and all the ſuckers cleared away from their roots. Never uſe the ſheers, but a knife in pruning your ſhrubs, and be careful to

cut away all the dead wood, and thin the branches, where they crowd upon one another. The ſtraggling branches ſhould alſo be taken away, and the ſhrubs kept clear from each other, ſo that every kind may be ſeen diſtinctly.

Thoſe flowering-ſhrubs and ever-greens that are ſet in pots ſhould be protected from the ſharpneſs of the froſt, by plunging the pots up to their rims in the ground in a dry part of the garden.

Litter ſhould alſo be laid round the ſtems of new planted flowering-ſhrubs and ever-greens, if the froſt becomes ſevere; let the litter extend as far at leaſt from the ſtems as the roots of the plants.

Let your new planted trees, &c. be ſupported with ſtakes, that they may not be diſplaced by the wind.

The ground between the flowering-ſhrubs and ever-greens ſhould be dug, obſerving to ſhorten the ſtraggling roots as you proceed, taking care not to diſturb the plants. This will not only be of ſervice to the ſhrubs, but alſo give the ſhrubbery a neat appearance.

You ſhould be very careful at this ſeaſon of the graſs-walks in the garden; they ſhould be frequently polled and rolled. The former ſhould be done with a pliable aſh-pole, fifteen or ſixteen feet long, at leaſt; with which you muſt break and ſpread the wormcaſts, whenever they appear upon the graſs. When this is done, let it be rolled with a wooden roller, which will take up all the wormcaſts, and leave your graſs-walks extremely neat.

This is alſo a proper ſeaſon, if the weather is open, for laying turf where wanted, for making or mending graſs-walks. Your turfs ſhould be three feet long, one foot broad, and an inch thick.

The beſt turf for gardens is that of heaths or commons, where great numbers of ſheep are paſtured.

As ſoon as the turf is laid, it ſhould be well beaten with a heavy wooden beater, and afterwards rolled with a large ſtone or iron roller.

Such of the gravel walks as are not laid up in ridges ſhould be kept clean from litter, and free from weeds; and if they are rolled as often as the weather will permit, it will be of great ſervice.

The Nursery.

In open weather, let the ground be dug between the rows of young trees and ſhrubs. It ſhould be dug one ſpade deep, and the earth turned fairly off the ſpade, that the weeds may be perfectly buried.

If the weather be froſty, let dung be laid on ſuch parts of the nurſery as require it. But obſerve that the dung be perfectly rotten, otherwiſe it will be prejudicial to the plants. If a little be laid between the rows of trees, and dug in, it will do them ſervice.

FEBRUARY.

Work to be done in the Kitchen Garden in February.

THIS is a buſy month for the gardener, provided the weather be fine and open; we ſhall therefore be careful to let our directions be full and intelligible.

Aſparagus.

It is not yet too late to make hot-beds for early aſparagus. In order to which let ſome good dung be procured and ſhook up into a heap, where it muſt lie about ten days, when it will be fit for your purpoſe. Let the bed be about three feet high, and the top made very level and ſmooth. When this is done, lay on the earth ſix or ſeven inches thick in every part, and make the ſurface ſmooth.

When your bed is thus prepared, raiſe a ridge of earth about ſix inches high from one end of the bed to the other, and place the roots againſt this ridge, as cloſe together as poſſible, till the whole bed is filled with them; obſerving to leave a ſpace two inches wide, at leaſt, on each ſide, to receive ſome earth againſt the outſide roots.

This being done, cover the crowns of the roots with light earth about two inches thick; which is all that is requiſite to be done till the buds begin to appear through the ſurface, when three or four depths of more earth muſt be laid upon the bed; by which means the tops of the roots will be covered five or ſix inches.

A quantity of ſharp pointed ſtakes, about two feet long, and alſo ſome thick bands or ropes of either ſtraw or hay muſt be procured. Theſe hay or ſtraw-bands are to be carried entirely round the bed, and faſtened down with the ſtakes at proper diſtances. Upon this border the frame is to be placed; which being done, the glaſſes muſt be put on, and covered every night with mats. Be very careful that the hay or ſtraw-bands be directly level with the ſurface of the earth in the bed.

In about thirty or forty days, the bed, if properly managed, will produce plenty of buds. But it is neceſſary to remember that the roots for this purpoſe be about three years old, never more than four. A three-light frame, if properly placed, will contain three or four hundred roots.

Cucumbers and Melons.

Your cucumbers and melon plants that have not ſuffered by any of the accidents that too often attend them at this ſeaſon, may now be tranſplanted into the hot-bed, where they are to produce their fruit. In order to this, let as much horſe-dung as will be ſufficient for making a hot-bed for one or more frames, three feet and a half high, be provided.

As ſoon as the dung is procured, let it be thrown up into a heap, where it muſt lay eight, ten, or twelve days, according to the condition it is in, or the quantity you intend to uſe. During this interval, let the heap be turned over once at leaſt; by which means the rank ſteam and ſtrong ſtench of the dung will fly off, and the ſeveral parts will become mellow, and mix together, when made into a bed: the heat will alſo be ſteady and laſting.

In

In making the bed, obſerve to ſhake ſome of the longeſt dung into the bottom; after which take it as it comes to hand, ſhake it equally on every part, and beat it down with the fork from time to time as you proceed. In this manner let the bed be carried up very evenly on each ſide, to the height of forty inches.

As ſoon as the bed is finiſhed, put on the frame and lights, which will at once defend it from the rain, and draw up the heat conſiderably ſooner. But it will be neceſſary to raiſe the lights a little, when it does not rain, that the ſteam may paſs off. When the bed has been made about a week, look it carefully over; and if it has ſettled unequally, take off the frame, level the bed, and replace the frame for good.

The bed muſt now be every day attentively examined: as ſoon as you find the violent heat is over, the earth may be laid upon the ſurface.

It is neceſſary to be remembered, that the earth choſen for this purpoſe be quite dry, and ſufficiently rich. Let about three quarters of a buſhel of this earth be laid in a round hillock about twelve inches high, in the middle of each light; and the ſpaces between the hillocks, quite to the hedge of the frame, be covered with the ſame ſort of earth, two or three inches thick.

As ſoon as you have put the earth in the above manner upon the bed, put on the glaſſes; and the next day, if the hillocks of earth be warm, level the top of each a little, ſo that they may be about ten inches high; and then begin to put in the plants.

This being done, take ſome pots of the ſtrongeſt plants, lay your hand on the ſurface of the pot, and take the ſtems of the plants carefully between your fingers: then turn the mouth of the pot downwards, and ſtrike the edge gently againſt the frame; by which means the plants, with the ball of earth to their roots, will come out entire. When this is done, make a hole in the middle of each hillock of earth, and place one pot of plants with the ball entire, in each hole, cloſing the earth well round the ball. Obſerve to cover the top of each ball about an inch, and to lay the earth cloſe round the ſtems of the plants.

About eleven or twelve o'clock the next day, give the plants a little water, obſerving to uſe ſuch as have ſtood long enough in the bed to take off the chillneſs. You ſhould alſo be careful to let very little, if any, of the water touch either the leaves or ſtems of the plants at this ſeaſon.

The only difficulty now remaining is to keep up a conſtant genial heat in the bed, that the plants may be kept in a continual growing ſtate.

But you muſt remember to raiſe the glaſſes a little every day when the weather is any thing favourable, that the plants may enjoy the freſh air; and to open the glaſſes more or leſs, in proportion to the ſharpneſs or mildneſs of the weather.

The firſt week or ten days after the plants are thus ridged out, you muſt be very careful to prevent the plants from having too much heat; for it ſometimes happens that a bed, after the mould and plants are in, will begin afreſh to heat, in ſo violent a manner as to burn the earth at the bottom of the hillocks; and unleſs ſome precaution be taken, the burning will ſoon reach the roots of the plants. It will therefore be neceſſary, during the firſt week at leaſt, to examine frequently the bottoms of the hillocks, by drawing away a little of the earth, and, if any burning appears, to remove the burnt earth, replacing it with new. At the ſame time let part of the earth at the bottoms of the hills be drawn away, leaving them only baſes ſufficient to ſupport the plants. And in this manner let them continue till the danger of burning is over.

When you give the plants air, you ſhould faſten a mat acroſs the ends of the lights, and let it hang down over the place where the air enters the frame; for this will, in a great meaſure, deſtroy the current of wind, ſo that it will not injure the plants, though there will be a proper proportion of air admitted; and at the ſame time the ſteam will have full liberty to evaporate.

Let the glaſſes be every night covered with mats, and if there be a ſtrong heat and conſiderable ſteam in the bed, let the lights be raiſed a little when you cover up, letting them remain ſo all night; by which means the ſteam will fly off through the matting, without the cold air being admitted to the plants.

As ſoon as the roots of the plants begin to appear through the ſides of the hillocks, let ſome earth be laid round them, and, about three days after, a little more. And in two or three days after that, you may earth the bed all over to the full thickneſs, ſo that the whole ſurface may be level, and equal with the tops of the hillocks.

The heat of the bed will in a little time begin to grow faint: as ſoon as this happens, let a lining be applied to either the back or front of the bed, or, if the heat be very low, to both.

Theſe linings ſhould be compoſed of dung prepared in the ſame manner as that for making the bed. They ſhould be about eighteen inches thick, and raiſed about five or ſix inches higher than the dung of the bed. Some earth ſhould be laid upon the top of the linings, to prevent the heat from finding a paſſage that way; for it would otherwiſe, in all probability, inſinuate itſelf into the frame, and prove detrimental to the plants.

If the plants are not already ſtopped at the firſt joint, let it be done now; for this will cauſe them to ſend out fruitful runners.

Cucumber and melon ſeeds ſhould be ſown at two or three different times this month, that a freſh ſupply of plants may be always ready, either for new beds, or for replacing any that may fail.

Cauliflowers.

The glaſſes ſhould be taken off the frames every mild day, that the cauliflower plants may enjoy a free circulation of the freſh air.

Some of the ſtrongeſt plants may, about the end of the month, be removed into the place where they are to continue. Let them be planted in a rich ſpot of ground, and a ſpace of thirty inches, or a yard every way, be allowed between the plants.

Thoſe cauliflower plants alſo which are under hand or bell-glaſſes, ſhould be thinned out when there are too many; one plant under each glaſs will be ſufficient, the reſt ſhould therefore be taken away. But remember to let the ſtrongeſt plant under each glaſs remain; and, at the ſame time, to draw up ſome earth round their ſtems. The plants taken up may be planted, at the above diſtance from each other, in another ſpot of ground.

At the beginning of this month ſome cauliflower ſeed ſhould be ſown on a ſlight hot-bed, that plants may not be wanting to ſucceed the early crop. The bed for this purpoſe ſhould be about twenty inches thick of dung; and the earth over it five or ſix inches thick. On the ſurface of this earth let the ſeed be ſown, and covered with light earth about a quarter of an inch thick. After which let the frame be put upon the bed.

As ſoon as the plants appear, they muſt have freſh air given them every day, by raiſing the glaſſes a conſiderable height. In mild weather the lights ſhould be taken entirely away, during the day-time; otherwiſe they would be drawn up very weak.

If moderate ſhowers of rain do not fall, the plants muſt be frequently ſprinkled with water.

Kidney-Beans.

A hot-bed may be made in the beginning of this month, for early kidney-beans.

In order to this ſome freſh horſe-dung ſhould be prepared as for other hot-beds; theſe ſhould be made about two feet and a half high, and long enough for one or more frames. Put on the frames, after making the ſurface of the bed ſmooth; and when the heat is moderate, cover the bed with rich light earth ſeven or eight inches thick. Then draw drills an inch deep, and a foot aſunder, from the back to the front of the frame. Drop the beans, about three inches aſunder, into the drills, and cover them an inch deep with earth.

The yellow, or liver-coloured, kidney-bean is the fitteſt for this purpoſe; though the ſpeckled, or dwarf kind will anſwer very well; for both theſe will continue bearing longer than the other ſorts. As ſoon as the plants begin to appear, the lights muſt be raiſed every day, that the plants may enjoy the benefit of the freſh air, which will ſtrengthen them greatly. Moderate ſprinklings of water at proper times will alſo be neceſſary when the plants are up.

Cabbages and Savoys.

Sugar-loaf and other early cabbage-plants ſhould be removed this month into the ſpot where they are to remain. Some rotten dung ſhould have been dug into the ground where theſe plants are to be ſet. Let the plants be ſet in rows two feet and a half aſunder, and the ſame diſtance between the rows.

A little cabbage ſeed ſhould be ſown about the latter end of the month for autumn uſe. Theſe will ſucceed the early plants, for they will be fit to cut in Auguſt and September.

About the latter end of the month, Savoy-ſeed may be ſown for the firſt time. Thoſe plants which are ſown now will be fit for the table in September; by October they will be finely cabbaged, and continue good till the end of November.

You may likewiſe plant this month, if not done before, both cabbages and ſavoys for ſeed.

Carrots, Parſneps, and Beets.

About the latter end of this month, a ſufficient ſpot of ground ſhould be prepared for carrots, parſneps, and beets.

The farther from trees, and the lighter the ground in which the roots are planted, the larger they will grow; for they thrive beſt in a light ſoil and open expoſure. The ground ſhould be dug one full ſpade deep at leaſt, and the clods carefully broken.

The ſeed ſhould be ſown in a dry, clear day, with an even hand, not too thick, and the ground equally raked afterwards. Each ſpecies of ſeed ſhould be ſown on different pieces.

Thoſe carrots, parſneps, and beets, that are intended for ſeed, ſhould be planted in rows two feet aſunder.

Beans.

At the beginning of this month let an open ſpot be dug for a crop of beans. The Windſor, Sandwich, and other large beans, are the moſt proper to plant at this ſeaſon; but they ſhould be planted in rows ſix inches aſunder, and the rows a full yard apart.

The Mazagan bean alſo may now be planted either in the garden, or the field; it is a good bearer, and will, in ſome ſoils, anſwer very well.

Peas.

About the beginning of this month a principal crop of peas ſhould be ſown in an open piece of ground. If you propoſe to ſow the marrowfats and other large peas, you ſhould draw drills for them, three feet and a half aſunder; but if you intend to place ſticks for the ſupport of theſe large kinds of peas, they ſhould be ſown in drills four feet aſunder.

The hotſpur, and other ſmall kinds of peas ſhould be ſown in drills a yard aſunder; if you intend to ſtick them, let the drills be forty inches aſunder.

All the crops, whether beans or peas, that are up and advanced any conſiderable height, ſhould now have earth drawn up their ſtems, which will at once ſtrengthen the plants, and protect them from the froſt. It ſhould however be done in a mild day.

Lettuces.

If the weather be mild about the beginning of this month, you may ſow ſeveral ſorts of lettuce-ſeeds on warm borders. The Coſs and Sileſia are the beſt kinds for ſowing at this ſeaſon: you may alſo ſow ſome of the cabbage and imperial lettuces. Let the ſeeds be ſown pretty thick, and raked in as ſoon as they are ſown.

But if the weather ſhould be cold at the beginning of the month, the ſeed of both the Coſs and Sileſia ſhould be ſown in frames, and covered occaſionally to protect it from the ſeverity of the weather. By this means you may procure ſtrong plants in unfavourable ſeaſons, and they may eaſily be tranſplanted when of a proper ſize.

Thoſe plants which have ſtood the winter in warm borders or frames, ſhould be thinned out, where they ſtand too cloſe, about the latter end of the month. But you muſt obſerve to thin them regularly, leaving them a foot diſtant each way; for they will require ſo much room to grow to their full ſize: the plants which are taken up ſhould be ſet in an open ſpot of rich ground, a foot diſtant every way.

Small

Small Salleting.

Let different ſorts of ſmall ſalleting be ſown once a week or ten days, viz. creſſes, muſtard, raddiſh, rape, and lettuce. The ſeeds ſhould be ſown in a frame, the earth light, and its ſurface laid very ſmooth.

Shallow drills ſhould be drawn from the back to the front of the frame, the ſeeds ſown in the drills, and covered about the fourth part of an inch thick. As ſoon as this is done, put on the glaſſes; but be ſure to give the plants air as ſoon as they are above the ſurface.

If the weather ſhould prove cold and wet, and ſmall ſalleting be much wanted, a ſmall hot-bed may be made for it. About fifteen inches thick of freſh horſe-dung will be ſufficient for this purpoſe, and the bed covered with earth four or five inches thick.

Let the ſeed be ſown on the ſurface, each ſort ſeparate, and as much earth ſifted over as will juſt cover it. Put on the frame, with the lights; and when the plants appear, let plenty of freſh air be given them.

If the weather be open and mild, you may, about the middle of the month, begin to ſow ſmall ſalleting on warm borders, in open ground.

Celery.

Prepare a ſmall bed of light rich earth in a warm border, in order for ſowing ſome celery-ſeeds, about the middle, or towards the latter end of the month. Let the earth be broken fine, the ſurface raked ſmooth, and the ſeed ſown not too thick upon it; after which let the ſeed be covered with light earth about a quarter of an inch thick.

Raddiſhes.

About the beginning of the month, let ſome part of a warm border be dug up in order to ſow a little raddiſh ſeed. The ſmall-topped raddiſh ſeed ſhould be ſown at this ſeaſon, to ſucceed thoſe of the ſame ſort that were ſown in the preceding month.

Another piece of ground ſhould be dug at the ſame time for ſowing ſalmon raddiſh-ſeed; becauſe theſe will ſucceed the ſmall-tops. Some more of the ſalmon raddiſh ſeed ſhould be ſown about a fortnight or three weeks after the former, that there may be a regular ſupply of theſe roots in their proper ſeaſon.

Spinnage.

If the weather be mild about the beginning of this month, ſome ſpinnage-ſeed ſhould be ſown in good ground well prepared to receive it. Let the ſeed be ſown thin, regular, and raked in.

Some ſow ſpinnage between the rows of cabbages, beans, &c. when ground is ſcarce. The ſmooth-ſeeded kind is the beſt to ſow now; and it will be proper to repeat the ſowings every fortnight or three weeks, if a regular ſupply of this vegetable be deſired.

Potatoes.

About the middle or latter end of this month, provided the weather be open, you may plant potatoes. Let them be ſet in rows two feet aſunder, and a foot or fifteen inches diſtant from one another in the rows. The roots ſhould be planted about five or ſix inches deep in the earth.

We have already given ample directions for planting this uſeful root in the fields. See the article POTATOE in the foregoing Dictionary.

Sorzonera, Salſafey, and Hamburg Parſley.

About the latter end of the month, let a ſpot of light ground in an open ſituation, be dug for the above herbs. The ſeed muſt be ſown thin and even, on ſeparate beds, and raked in equally.

Thyme, Marjoram, Savory, and Hyſſop.

Theſe herbs ſhould be ſown upon a dry ſpot of light, rich ground, in a warm ſituation, about the latter end of the month. They ſhould be ſown thinly on ſeparate beds; and the ſeeds raked in.

Parſley, Coriander, and Chervil.

Any time this month, when the weather is open, will be proper for ſowing parſley, coriander and chervil. The ſeed ſhould be ſown in ſhallow drills, and covered with about a quarter of an inch of mould.

Garlick and Shallots.

The beds intended for planting garlick and ſhallots ſhould be about four feet wide, and the roots ſet in rows nine inches aſunder, and ſix inches diſtant from one another in the rows.

Muſhrooms.

You muſt take particular care to defend your muſhroom beds from heavy rains and froſt, as either will deſtroy the ſpawn. The beds ſhould be entirely covered with ſtraw, twelve or fifteen inches thick at leaſt. And if you ſhould at any time perceive that the wet has penetrated through any part of the covering, let that part be removed, and replaced with clean dry ſtraw.

Horſe-Raddiſh.

Horſe-raddiſh is propagated either by cuttings, or by planting the tops of the old roots; in the following manner:

Let the trenches in which the cuttings, &c. are to be planted, be dug fifteen inches deep at leaſt. When the trench is ready procure ſome knotty roots, and cut them into pieces, about an inch or two in length, obſerving that each piece be furniſhed with eyes or buds; but it will ſtill be better if you can procure a quantity ſufficient for your purpoſe, of the tops or crowns. Theſe may be cut from the tops of ſmall off-ſets, which grow from the main roots, and alſo from the old roots when they are taken up for uſe.

When you have furniſhed yourſelf with a ſufficient quantity of cuttings or crowns, place them along the bottom of the trench ſix inches from each other. Then let the next trench be dug in the ſame manner as the firſt, throwing the earth taken out of the latter into the former

former trench, over the plants. In this manner you are to proceed with the reſt of the trenches till the whole quantity intended is planted.

The Fruit-Garden.

Pruning Fruit-trees.

As this is the peculiar month for pruning fruit-trees, we ſhall conſider this work in general, before we proceed to particular trees.

No part of gardening is perhaps of more general uſe than that of pruning, and yet it is very rare to ſee fruit-trees ſkilfully managed. Almoſt every gardener pretends to be a maſter of this buſineſs, though very few rightly underſtand it. Indeed it requires a ſtrict obſervation of the different manners of growth of the ſeveral ſorts of fruit trees; ſome require to be managed one way, while others muſt be treated in a quite different manner; and this is to be known only by practice, and carefully obſerving how each kind is naturally diſpoſed to produce its fruit; ſome ſorts growing on the ſame year's wood, as vines; others produce their fruit for the moſt part upon the former year's wood, as peaches, nectarines, &c. and others upon curſons or ſpurs, which are produced upon wood from three, four, or five, to fifteen or twenty years old, as pears, plums, cherries, &c. In order therefore to manage fruit-trees rightly, proviſion ſhould always be made to have a ſufficient quantity of bearing wood, in every part of the trees; and, at the ſame time, not to have a ſuperfluity of uſeleſs branches, which would only tend to exhauſt the ſtrength of the trees, and cauſe them to decay in a few years.

Pruning fruit-trees, is founded on the following reaſons: firſt, To preſerve trees longer in a vigorous bearing ſtate: ſecondly, To render the trees more beautiful to the eye: and thirdly, To cauſe the fruit to be larger, and better taſted.

1. It preſerves a tree longer in a healthy bearing ſtate; for by cutting off all the ſuperfluous branches, ſo that no more are left upon the tree than are neceſſary, or than can be properly nouriſhed, the root is not exhauſted in ſupplying uſeleſs branches, which muſt afterwards be cut out, whereby much of the ſap will be uſeleſsly exhauſted.

2. By ſkilful pruning of a tree it is rendered much more pleaſing to the eye; but we would not here be underſtood to recommend a ſort of pruning too much practiſed of late; namely, the drawing a regular line againſt the wall, according to the ſhape and figure they would reduce the tree to, and cutting all the branches, ſtrong or weak, exactly to the chalked line; the abſurdity of which will ſoon appear to every one who will be at the pains of obſerving the difference of thoſe branches ſhooting the following ſpring. All therefore we would be underſtood to mean by rendering a tree beautiful is, that the branches are all pruned according to their ſeveral ſtrengths, and nailed at equal diſtances in proportion to the different ſizes of the leaves and fruit; and that no part of the wall, within the extent of the tree, be left unfurniſhed with bearing wood. A tree well managed, though it does not repreſent any regular figure, will ſtill appear very beautiful to the ſight, when it is thus dreſſed, and nailed to the wall.

3. It is of great advantage to the fruit, for the cutting away all uſeleſs branches, and ſhortening all the bearing ſhoots according to the ſtrength of the tree, will render it more capable of nouriſhing thoſe which are left remaining, ſo that the fruit will be much larger, and better taſted. And this is the advantage which thoſe trees againſt walls or eſpaliers have over ſtandards, which are permitted to grow as they are naturally inclined; for it is not their being trained to a wall or an eſpalier, which renders their fruit better than ſtandards, but becauſe the roots have a leſs quantity of branches and fruit to nouriſh, and conſequently their fruit will be larger and better taſted.

Having thus conſidered the nature of pruning in general, we ſhall now proceed to the particular ſorts of trees that require pruning at this ſeaſon of the year.

Prune Standard Fruit-trees.

Such ſtandard fruit-trees, in the orchard and fruit-garden, as require pruning, may be dreſſed this month. You ſhould be careful to cut from thoſe trees all dead wood and very old branches, and all ſuch as grow in a rambling manner acroſs others. Whenever you ſee the branches crowded together, let ſome be cut away, ſo that the principal branches may ſtand clear of each other. At the ſame time be very careful to clear the branches from moſs.

Prune Dwarf Apples, Pears, &c.

If poſſible, let all your apples, pears, and cherries, planted either againſt walls or eſpaliers, be pruned this month.

And in performing this operation, be careful to cut away all the very old branches, and ſuch as are naked, or deſtitute of bearing wood. At the ſame time be careful to leave room ſufficient for training the young wood and full bearing branches to the wall or eſpalier, in a regular and handſome manner.

Wherever you obſerve the branches to ſtand too cloſe together, let the moſt irregular of them be taken away.

If wood be wanting, leave ſome of the beſt ſituated of the laſt ſummer's ſhoots, in order to fill up the vacant places. But where theſe ſhoots are not wanted for the above purpoſe, let every one of them be cut off cloſe to the part from whence they proceeded, leaving no ſpurs but what are naturally produced.

It is neceſſary to obſerve, that the ſhoots or branches of theſe trees muſt not be ſhortened, but left at full length, and in that manner trained cloſe and even to the wall, &c. about ſix inches diſtant from each other.

Prune Gooſeberry and Currant Trees.

If your gooſeberry and currant trees were not pruned laſt month, it muſt be done now. In doing this obſerve to cut away all the irregular branches; that is, all thoſe that grow acroſs, or in a ſtraggling manner from the reſt.

If you obſerve the branches in general to ſtand ſo cloſe as to interfere with one another, let them be thinned out to proper and equal diſtances, ſo that every branch may ſtand clear of the other: they ſhould be, at leaſt, ſeven or eight inches apart.

Gooſeberry

Gooſeberry or currant-trees may be planted any time this month. But they ſhould never be planted nearer than ſeven or eight feet from one another.

Prune Vines.

If you have any vines that were not pruned laſt month, let it be done now, but the earlier the better. Obſerve in pruning vines to cut out the old naked branches, in order to make room for the bearing-wood; which are properly the laſt year's ſhoots. Care muſt therefore be taken to leave a proper ſupply of the ſtrongeſt of the laſt year's ſhoots in every part of the tree. Care ſhould alſo be taken to have a ſucceſſion of young wood coming up regularly from the parts of the vine near the bottom of the wall.

Let the branches or ſhoots in general be left at equal diſtances, and about eight or nine inches from each other.

At the ſame time you muſt obſerve to ſhorten each ſhoot in proportion to its ſtrength, ſome to three, four, or five eyes long, and let the cut be made ſloping, about an inch above and behind the eye.

Raſpberries.

Raſpberries, where any remain unpruned, ſhould, if poſſible, be pruned this month. In pruning raſpberries, obſerve to leave three of the laſt year's ſhoots ſtanding on each root, to bear fruit the next ſummer; but all above that number muſt be cut away cloſe to the ſurface of the ground; and all ſtraggling ſhoots between the rows muſt alſo be taken away. All the dead wood muſt be cleared away.

All the ſhoots that are left ſhould be ſhortened about one third of their original length.

When the pruning is finiſhed, dig the ground between the plants; obſerving as you dig to clear away all the ſtraggling roots, and leave only thoſe belonging to the ſhoots which are left to bear.

If new plantations of raſpberries be wanted, they may be made this month. The plants ſhould be ſet three feet diſtance from each other in the rows, and the rows four feet aſunder.

Strawberries.

Strawberries ſhould now be cleaned, and have their ſpring dreſſing. Firſt pull or cut off all the ſtrings or runners from the plants, and clear the beds from weeds and litter of every kind. When this is done, looſen the ground between and about the plants, adding a little freſh earth between the rows, and cloſe round every plant; this will greatly ſtrengthen the plants, and cauſe them to produce large fruit.

You may now plant ſtrawberries, but the beſt time is in Auguſt and September. Let a proper piece of ground be prepared for theſe plants: if the ſoil be loamy, ſo much the better; but whatever it be, ſome rotten dung muſt be dug in.

Let your ground be now divided into beds four feet wide, with alleys between them at leaſt eighteen inches wide. Let the ſtrawberry plants be ſet in rows a foot aſunder, allowing the ſame diſtance between plant and plant in the rows.

Planting Fruit-Trees.

Fruit-trees of all ſorts may be planted any time this month, when the weather is mild and open.

Peaches, apricots, and nectarines ſhould never be planted cloſer than fifteen feet from one another; but if you allow eighteen feet, it will be ſtill better.

Apples, pears, plums, and cherries, for walls or eſpaliers, ſhould be planted eighteen feet aſunder; twenty will not be too much. For though theſe diſtances ſeem large at firſt, when the trees are ſmall, yet in ſeven years you will be ſufficiently convinced of the benefit that will ariſe from planting them in this manner.

Standard trees ſhould be allowed full thirty feet diſtance: none ſhould be planted nearer in a garden.

Care ſhould be taken in ſetting fruit-trees that they be not planted too deep; for that is a more material article than moſt gardeners imagine. And be very careful to open for each tree a hole large enough to receive all the roots freely, without preſſing them againſt the ſides.

When the holes are dug, and the trees ready to be planted, let their roots be pruned, and ſuch as are broken or bruiſed, taken away. Then ſet the tree in the hole, carefully obſerving that all the roots ſpread freely as they ought to do.

Break the earth well, and throw it in equally about the roots, ſhaking the tree gently that the earth may fall in cloſe between the roots and their fibres; when the earth is all thrown in, tread the earth gently, to fix the tree in a proper poſition.

Let all ſtandard trees be ſupported with ſtakes, as ſoon as they are planted, that the wind may not rock them about.

You muſt alſo ſecure dwarf-trees againſt the power of the wind, by faſtening them to the wall, or rails of the eſpalier.

As ſoon as you have finiſhed your pruning and nailing, let all the fruit-tree borders be neatly dug; or, if they have been dug before, let the ſurface be looſened, where it has been trampled in doing the neceſſary work about the trees. This will be very ſerviceable to the trees, and, at the ſame time, give the borders a clean and neat appearance.

The NURSERY.

You muſt now finiſh your digging the ground between the rows of all kinds of young trees and ſhrubs.

Stocks to Bud and Graft upon.

You ſhould now make new plantations of ſtocks to bud and graft the various kinds of choice fruit upon.

Theſe ſtocks ſhould be planted out as ſoon in the month as poſſible, if the weather will permit. Let them be planted in rows two feet and a half aſunder, and fifteen inches at leaſt from one another in the rows.

All the ſtocks that were budded laſt ſummer ſhould now be headed down. This ſhould be done with a ſharp knife, obſerving to cut the head off about four inches above the bud.

Grafting.

This curious operation may be performed any time this month, provided the weather be mild.

The moſt proper ſort to begin with are pears, plums, and cherries: and theſe kinds generally ſucceed beſt, when graſted ſome time in the laſt fortnight of this month. Apples may either be grafted at the ſame time, or deferred a fortnight longer.

When grafting is to be performed, you ſhould begin to prepare for it about the beginning of the month.

The firſt thing neceſſary to be done is to collect the grafts. In the choice of theſe the following directions ſhould be carefully obſerved: Firſt, That they are ſhoots of the former year. Secondly, That they are taken from healthy fruitful trees. And, thirdly, That you preſer thoſe grafts which are taken from the lateral or horizontal branches, to thoſe taken from the perpendicular ſhoots. Theſe grafts ſhould be cut off from the trees before the buds begin to ſwell, which is generally three weeks or a month before the ſeaſon for grafting; therefore when they are cut off, they ſhould be laid in the ground with the cut downwards, burying them half their length, and covering their tops with dry litter, to prevent their drying: if a ſmall joint of the former year's wood be cut off with the cion, it will preſerve it the better: and when it is grafted, this may be cut off; for the grafts never muſt be cut to a proper length before they are inſerted into the ſtocks; but till then, the ſhoots ſhould remain their full length, as they were taken from the tree, which will preſerve them better from ſtriking. If theſe grafts are to be carried to a conſiderable diſtance, it will be proper to put their cut ends into a lump of clay, and to wrap them up in moſs, which will preſerve them freſh for a month or longer: but theſe ſhould be cut off earlier from the trees than thoſe which are to be grafted near the place where the trees are growing.

The reaſon for grafting is, that as all good fruits have been accidentally obtained from ſeeds, ſo theſe when ſown will often degenerate, and produce ſuch fruit as are not worth cultivating; but when the ſhoots, cions, or grafts, are taken from ſuch trees as yield good fruit, theſe will never vary from their kind, whatever be the ſtock or tree on which they are grafted.

The moſt proper ſeaſon for grafting is in the ſpring, juſt before the riſing of the ſap, or at leaſt before it riſes in any great quantity: but the weather muſt be neither froſty nor wet; nor ſhould the wind blow very bleak or ſtrong when this operation is performed: for on theſe circumſtances, and upon the exact joining of the inner bark of the cion with the inner bark of the ſtock, ſo that the ſap which flows between the bark and the wood may be communicated from the one to the other, the ſucceſs of graſting chiefly depends.

The implements neceſſary for graſting are, fine ſmall hand-ſaws to cut off the heads of large ſtocks; a good ſtrong knife with a thick back to make cleſts in the ſtocks; a ſharp penknife to cut the graſts; a grafting chiſſel, and a ſmall mallet to pare away the wood; baſs, or woollen yarn, to tie the graſts with; and a quantity of clay, or cement, properly prepared, to lay over the inciſions, in order to prevent their bleeding, and keep out the air.

The method of preparing the clay intended for this purpoſe, is to mix thoroughly together a quantity of ſtrong fat loam, ſome new ſtone-horſe dung broken into ſmall bits, a little tanners hair, or ſtraw, cut very ſmall, with a little ſalt, and as much water as will make the whole of the conſiſtence of pretty ſtiff mortar.

The cement or compoſition which ſome have of late uſed, and which has been found to anſwer the deſign of keeping out the air better than the above clay, is made of turpentine, bees-wax, and roſin, melted together. This compoſition, when of a proper conſiſtence, is laid about a quarter of an inch thick, upon the cut part of the ſtock round the graft: and has this farther advantage over the clay, that there is no danger of its being hurt by froſt; for cold hardens it; and when the heat of ſummer comes on, by which time it is no longer wanted on the tree, it will melt and fall off without any trouble.

Among the ſeveral methods of grafting hitherto known, the following are moſt approved, and generally practiſed.

Cleft-Grafting, called alſo Stock, or Slit Grafting.

This is uſed chiefly for middle-ſized ſtocks, from one to two inches in diameter. The ſeaſon for it is in the months of February and March; and the method, as now practiſed, is thus:

The head of the ſtalk being ſawn, or cut off, with a ſlope, ſmooth and clean, a perpendicular cleft is made therein, about two inches deep, with a ſtrong knife, or chiſſel, from the top of the ſlope, as near to the pith as may be without touching it. In this cleft, the grafting chiſſel, or a wedge, is put to keep it open. The graft or cion is prepared by cutting it aſlope, in form of a wedge, to ſuit the cleft, only leaving a ſmall ſhoulder on each ſide; and when cut, it is to be placed exactly in the cleft, ſo as that the inner bark of the cion may aptly, and cloſely, join to the inner part of the bark, or rind of the ſtock; in the dexterous performance of which, the chief part of the art of grafting conſiſts. That ſide of the cion which is to be placed outward, at the part where it is cut wedge-wiſe and inſerted into the cleft of the ſtock, ſhould be much thicker than the other ſide, the better to facilitate the exact joining of its rind to that of the ſtock; for if theſe two do not unite, the graft will not ſucceed. The rind of the ſtock choſen for this way of grafting ſhould therefore not be too thick; becauſe it will then be the leſs manageable. If the cleft pinch too tight, a ſmall wedge may be left in it to bear the ſtreſs. As ſoon as the graft is properly fixed, the cleft ſhould be cloſely covered over with clay, or, which ſome think better, with moſs, or the freſh bark of a tree bound on with ozier.

When this method, which is the moſt ancient, and moſt common, manner of grafting, is uſed to ſtocks that are not ſtrong, a ligature of baſs ſhould be made around the ſtock, to prevent the opening of its ſlit; and the whole ſhould then be clayed over, or covered with the cement before deſcribed, to hinder the air from penetrating into the ſlit, ſo as to deſtroy the graft, only two eyes of which ſhould here be left above the clay, for ſhooting.

The

The ſtraighteſt and ſmootheſt part of the ſtock ſhould always be preferred for grafting, in whatever way this operation is performed.

Grafting in the Rind, or Shoulder Grafting.

This is likewiſe called ſlicing and packing, to diſtinguiſh it from grafting in the bark, which will next be ſpoken of, and is performed in the following manner, about the latter end of March, or the beginning of April, on more ſlender ſtocks than thoſe which are commonly uſed for cleft-grafting.

The top of the ſtock is cut off in a ſmooth, ſtraight place: then the cion, or graft, is prepared by cutting it on one ſide from the joint, or ſeam, down ſlope-wiſe, making the ſlope about an inch, or an inch and an half long; and obſerving it is bent, ſo that the cion may ſtand nearly upright when it is fixed to the ſtock. At the top of the ſlope, a ſhoulder is made, whereby it is to reſt on the crown of the ſtock. The whole ſlope muſt be plain and ſmooth, that it may lie even to the ſide of the ſtock. The length of the cion uſed here may be about four inches from the ſhoulder, for a ſtandard tree; but for a dwarf, or wall-tree, it may be ſix inches. When the cion is prepared, the outſide of its ſloped end, from the ſhoulder downward, is applied to the weſt, or ſouth-weſt ſide of the ſtock, and its length and breadth meaſured thereon; which done, the bark of the ſtock (but not any of its wood) is cut away to thoſe dimenſions, that the cut part of the cion may be fitted in as exactly as poſſible. In doing this, regard muſt be had to the bigneſs of the ſtock, and the thickneſs of its bark, in order to proportion thereto the length and breadth of the cut part of the cion; otherwiſe the paſſages of the ſap in the ſtock and cion will not meet, and the cion will then of courſe periſh. When the cut part of the cion is exactly fitted to, and laid on that of the ſtock, they are bound together with woollen yarn, and covered with clay an inch above, and as far below, the head of the ſtock; working it round the coin, till it become ſharp at top, that the rain may run down it.

This method has ſeveral advantages over the former. Among theſe are, that the wound heals up ſooner, and that, in the mean time, it is in leſs danger from the weather: that it does leſs injury to the ſtocks and grafts, by avoiding all ſevere ſplittings and pinchings; that the bark is more eaſily placed in the paſſage of the ſap here, than in the cleft; that the graft thrives and ſhoots with greater vigour, and bears ſooner in this way than in that; and that it is practicable on ſmaller ſtocks than the other, which muſt have a good body, and conſiſtence, before they can bear cleaving.

Grafting in the Bark.

This operation is performed thus. Prepare the ſtock and cion as for grafting in the rind, both as to time and manner; but, inſtead of cutting out the bark of the ſtock, ſlit it down, on the ſouth-weſt ſide, from the top, almoſt as long as the ſloped part of the cion, and at the top of the ſlit looſen the bark with the point of your knife. Then thruſt an inſtrument, made of very hard wood, ivory, ſilver, or the like, and formed at the end like the ſlope-end of the cion, but much leſs, down, between the bark and wood, to make room for the cion; which being put in, the bark is to be ſo managed, as that it may cloſe exactly to the ſtock and edges of the cion, and the whole is then to be bound up, and covered as before.

Whip-Grafting, or Tongue-Grafting.

This is proper for ſmall ſtocks, from an inch diameter to a quarter of an inch, or even leſs. Mr. Worlidge, Mr. London, Mr. Miller, and others, ſpeak of it as the moſt effectual way of any, and that which is moſt in uſe, becauſe the cion covers the ſtock much ſooner in this method than in any other; for here the cion and the ſtock muſt always be of the ſame thickneſs. There are three ways of performing it, and all of them may be practiſed ſomewhat later than either of the foregoing.

The firſt is, to ſlope the cion off a full inch, or more; then to do the ſame to the ſtock; and afterwards to tie the one to the other, with baſs or yarn, ſo as to join them cloſely at every part, but particularly at the rind; and then to cover the joint carefully with well tempered clay. The baſs uſed for this, or for any other binding, ſhould be taken from a ſound mat, and be ſoaked in water for ſome hours, to increaſe its ſtrength, and render it the more pliable.

The ſecond way is, to make a ſhoulder in the graft, and, the head of the ſtock being cut off and ſmoothed, to join it as in grafting in the rind.

The third method, which is an improvement of the laſt, is properly named tipping or tonguing. This is done by cutting the ſtock off ſlanting, as before, and leaving at its upper ſide a thin piece, or tongue, as it is called, of the wood, pared away like the lower end of a cion. The cion is then ſloped, and tongued, in the ſame manner as the ſtock, and a ſlit is made in each of them, downward in the ſtock, and upward in the graft, on the ſide oppoſite to the tongue, ſo that each may receive the tongue of the other. The cion is then joined to the ſtock, as cloſely as can be, particularly at the bark; a ligature is made round them with baſs or woollen yarn, and the engrafted part is well covered with clay or cement.

Side Grafting.

In this, the cion is prepared as in whip-grafting; but the head of the ſtock is not cut off at the time of performing the operation. Inſtead of that, ſo much of the bark as the cion will cover is pared off from the weſt-ſide of the ſtock; then both the cion and the ſtock are ſlit in the laſt mentioned manner of whip-grafting, and they are bound together, and cloſed up with clay. At the year's end, the top of the ſtock is cut off at the grafted place, ſlopewiſe; and the wound is covered with clay or cement.

Crown-Grafting.

This is only practiſed in the larger trees, which are capable of receiving a number of grafts, and are too big to be cloven; for theſe, the head or main branches, being cut off horizontally, four or more grafts are placed round the ſtock, between the bark and the rind, ſomewhat in the manner of a crown. The moſt proper time for performing this is about the latter end of March, or

the beginning of April. After the intended number of cions are inſerted, which is done exactly in the ſame manner as that already delivered for graſting in the rind, the whole crown of the ſtock is well clayed over, and only two eyes of each cion are left uncovered; that being ſufficient for their ſhooting.

This method of graſting was more practiſed formerly than it is at preſent; many people having been diſcouraged by the ill ſucceſs that has frequently attended their cions, which have been blown out of the ſtock, by ſtrong winds, after they had made large ſhoots, and even after they had grown there five or ſix years. But this accident may be prevented, by tying the cions to ſtakes faſtened to the tree, till they are ſo firmly fixed, as to have almoſt covered the ſtock.

Root Grafting.

This is a modern invention, the deſign of which is ſomewhat different from that of any of the former methods; this being for the propagation, or multiplication, of plants already fitted to produce their fruit.

To perform this, take a graft, or ſprig, of a young tree, which you intend to propagate, and a ſmall piece of the root of another tree of the ſame kind, or of a like genus, and whip-graft them together; obſerving that the but-ends of the graft and root be well united, and that the rind of the root join cloſely to that of the graft. Theſe may, afterwards, be planted out at pleaſure, and the piece of root will collect the nutritive juices, and feed the graft, as the ſtock does the other way.

This method of propagation is very eaſy and expeditious; roots being more plentiful than ſtocks: by this means the pieces of roots of one crab-ſtock, for example, or of one apple-ſtock, will ſerve for twenty or thirty apple grafts; and the like of other trees. It is alſo an excellent way for raiſing of tender trees, which will hardly bear being grafted in the ſtock. Add, that trees thus grafted bear ſooner, and are more eaſily dwarfed than thoſe done any other way.

The only objection againſt this method is, that the young tree grows but ſlowly at firſt, which is occaſioned by the ſmallneſs of the root that feeds the graft; for in all trees the head muſt follow the increaſe of the roots, from whence it hath its nouriſhment.

Reiterated Grafting, or Grafting by a double or triple inciſion.

This is another method mentioned by Agricola, whoſe work, though chimerical enough in many reſpects, contains, notwithſtanding, ſeveral good things. To perform this, firſt graft a good cion on a ſtock, and cut it away to one half, or a third part; then fix to that remaining part of the cion another graft, of a better kind; and to that a third; for the oftener the tree is grafted, the finer fruit it produces.

By this method the author above-mentioned aſſures us, that he produced muſcat pears, which were admirable, making at firſt uſe of a ſtock grafted with a pound-pear, on which he grafted a ſummer bon-chretien; and when the branch of this laſt had ſhot, he graſted on it a cion of a bergamot, which he alſo cut, and graſted on it a cion of a muſcat pear.

Graſting of Branches.

This is alſo commended by Agricola, as a very certain and profitable operation; beſt practiſed on large, or full-grown, and even old trees.

To do this, half or more of the branches muſt be lopped off, and grafts of three or four years old be applied to them, taking care to have ſtakes, or other things, to ſupport them againſt the wind, &c.

He adds, that by this method you will have, perhaps, the ſame year, or at leaſt the ſecond or third, ſuch a quantity of fruit, as the youngeſt and ſoundeſt tree would hardly produce.

Graſting by approach, called alſo Inarching, and Ablactation.

This is uſed only when the tree intended to be grafted, and that from which the graft is to be taken, ſtand ſo near, or can be brought ſo near to each other, that they may be joined together. The method of performing it is this: the branch to be inarched is fitted to that part of the ſtock where it is to be joined; the rind, and part of the wood, of one ſide of that branch, is then pared away, very ſmooth and even for the length of three inches; and afterwards the other branch, which is to ſerve for the ſtock to which the graft is to be united, is ſerved in the ſame manner, ſo that the two may join cloſely and equally together, that the ſap veſſels may meet. A little tongue is then cut upwards in the graft, and a ſlit is made in the ſtock to receive it; ſo that when they are joined, the tongue prevents their ſlipping, and the graft is the more cloſely united to the ſtock. When they are thus placed exactly together, they muſt be tied with baſs, worſted, or ſome other ſoft thing; and the place of junction muſt be well covered over with grafting clay, to prevent the air from drying the wound, and the wet from rotting the ſtock. A ſtake muſt alſo be fixed in the ground, and both the ſtock and the graft muſt be tied thereto, to prevent their being diſplaced by the wind. When they have remained in this ſtate four months, they will be ſufficiently united, and the graft may then be cut off from the mother-tree, obſerving to ſlope it cloſe to the ſtock. It is of great ſervice to the graft then to lay a freſh coat of clay all round the grafted or joined part. This operation ſhould be performed in April or May, that the graft may be perfectly united to the ſtock, before the enſuing winter. It is chiefly practiſed upon oranges, myrtles, jaſmines, firs, pines, and ſome other trees, which do not ſucceed well in the common way of grafting or budding. But though orange trees are here mentioned among the reſt, this practice is not to be adviſed for them, or for any other trees, if they are intended to grow large; for that they hardly ever do in this method; and accordingly it is ſeldom uſed but for the curioſity of having a young plant with fruit upon it, in a year or two from its having been raiſed from the ſeed. This is, indeed, effected by inarching a bearing branch into a young ſtock: but the plant ſo treated ſeldom lives long.

The walnut, fig, and mulberry, will alſo take by this method of grafting, though neither of them will ſucceed in any other way; but ſtill they, like all other trees that are thus managed, will remain weak, and ſtinted in their growth, beſides the ſhortening of their otherwiſe uſual time of duration.

All

All grafts, particularly of young cions, are subject to be injured by birds: but that may be prevented by binding some small bushes about the tops of the stocks.

The binding of the grafts, whether it be of bass or yarn, should be loosened at least, if it be not entirely taken off at Midsummer, or thereabout, lest its then too great tightness (as the stock will have increased in bulk, and the binding, perhaps, have been swelled, and consequently shrunk by the weather) should injure the plant.

Propagating by Layers.

This is the best season for laying down the branches of all kinds of exoticks and shrubs.

Layers may also be now made of all such hardy shrubs and trees as are increased by this method, provided it was omitted between Michaelmas and Christmas; and it will succeed with many kinds.

In order to form layers of any kind of trees or shrubs, let the ground be dug round the plant that is to be laid; and as you proceed bring down the shoots or branches regularly, and lay them along in the ground, fastening them securely there with hooked pegs. This being done, let all the young shoots on each branch be neatly layed and covered three or four inches deep with earth, leaving the top of each three or four inches out of the ground.

By next Michaelmas most kinds of layers that are layed now will be tolerably well rooted, and fit to be transplanted.

Transplant Layers.

Let the layers of such trees and shrubs as were layed down last year, and not yet taken off, be now separated; and as soon as taken off, trimmed and planted in rows in an open situation. The rows should be eighteen or twenty inches asunder, and the plants set at about fifteen inches from each other in the rows.

Plant Cuttings of Gooseberries and Currants.

The best method of propagating gooseberries and currants is by cuttings, and this work may now be performed.

Observe to take your cuttings from such of the last year's shoots as are strong. They should be from ten to twelve or fifteen inches in length. Let them be planted in rows twelve inches at least asunder, and set each cutting about half way into the ground.

Experience has sufficiently shewn that gooseberries and currant-trees raised from cuttings always produce fruit remarkably large and well tasted; while the fruit produced by trees raised from suckers is generally small and ill tasted.

Plant Cuttings of Honey-Suckles.

This is still a good season for planting the cuttings of honey-suckles and other hardy flowering shrubs and trees.

The cuttings should be shoots of the former year's growth; let the strongest shoots be chosen for this purpose; and let them be from six to twelve inches long. Plant these in a shady situation, in rows twelve inches asunder, and six or eight between each in the rows. They must be set about half way in the earth.

By next October, most of the cuttings planted now, will be sufficiently rooted, and therefore may be removed at that season.

Transplant Flowering Shrubs.

Flowering shrubs of all kinds may be now safely transplanted, provided the weather be mild and open. Observe to let the whole of this work be completed by the latter end of this month, if the weather will permit.

Transplant hardy Fruit and Forest Trees.

All kinds of hardy fruit and forest trees may be removed any time this month; but the sooner it is done the better; provided the weather be mild and open.

Pruning.

All flowering-shrubs that want pruning must now undergo the operation; for you must finish your pruning this month.

You should observe to train all your plants with a single stem; and if you find their heads growing irregular, cut out or shorten such shoots as you think necessary, in order to form the head into some handsome form.

Be careful to take away all suckers that rise from the roots of any kind of shrubs. The best of them may be planted out at proper distances, and in two or three years time, they will become good plants.

Sow the Stones of Plums, &c.

The stones of plums, and kernels of other fruits, should now be sown in order to raise a supply of stocks to bud and graft upon.

The sooner they are sown in the month the better, provided the weather be mild and open. Let the spot chosen for this purpose be in a sheltered situation, and the soil perfectly clean and light. The stones should be sown on beds about four feet wide, and covered about an inch deep with eath.

The Pleasure or Flower-Garden.

Sow the Seeds of the Auricula and Polyanthus.

The seeds of the auricula and polyanthus may be sown any time this month, when the weather is mild and open. The plants will rise freely from this sowing, and thrive well. A warm spot of ground should be chosen for the purpose, unless you chuse to sow the seed in pots or boxes filled with rich light earth.

But which ever method be used, the seeds should be sown tolerably thick, and covered about a quarter of an inch deep with rich light earth.

If the seeds are sown in pots or boxes, place them in a situation well defended from the northerly winds, and open to the morning and mid-day sun: in about two months they must be removed into a more shady situation.

Sow curious Annual Plants.

The choicest kind of annual plants, such as doub'e balsams, cockscombs and tricolars, globe amaranthus, marvel

marvel of Peru, diamond ficoides, or ice plants, egg plants, China aſters, &c. require a hot-bed in order to their blowing early in any tolerable degree of perfection.

Let therefore ſome new horſe-dung be thrown up in a heap about the middle of this month, and in about eight or ten days it will be in a proper condition for making the bed; which ſhould be about two feet and a half thick of dung. Let the ſurface be levelled, and the frame and glaſſes placed upon it.

As ſoon as the burning heat of the bed is over, lay on a quantity of rich, light, and perfectly dry, earth, ſufficient to cover the bed five or ſix inches deep.

Make the ſurface of the earth level and ſmooth, and ſow the ſeeds on the ſurface, each ſort ſeparate, covering them about a quarter of an inch deep with light earth, well ſifted. Let the glaſſes be covered over-night with mats; and give the plants now and then little ſprinklings of water.

Sow Ten-Week-Stocks.

A little of the ſeed of ten-week-ſtocks may be ſown at the latter end of the month, in order to raiſe a few plants for blowing early in the ſummer.

It will be beſt ſown on a ſlight hot-bed, as the plants will be much ſtronger, and flower three weeks or a month earlier than they would otherwiſe do. But as the plants are tolerably hardy, they may be ſown in a warm border.

Let the ground be neatly dug, and the ſeed ſown tolerably thick, in a bed about three feet broad. Arch the bed over with hoops, and cover it every night with mats in bad weather. If you have a ſpare frame and glaſs to cover the bed, or hand-glaſſes for the plants, they will thrive the better.

Sow hardy Annual Flowers.

If the weather be mild, dry, and open, about the latter end of the month, many ſorts of annual flower-ſeeds may be ſown in the warm borders, and other parts of the flower-garden; particularly the lark-ſpur, flos adonis, convolvulus, lupines, ſweet ſcented and Tangier peas, candy-turf, dwarf lychnis, Venus looking-glaſs, Venus navel-wort, lobels, catchfly, dwarf poppy, dwarf annual ſun-flower, oriental-mallow, lovetera, hawk-weed, &c.

You muſt obſerve to ſow all the above ſeeds in the places where the plants are intended to flower; for they will not ſucceed if tranſplanted.

The beſt method therefore of cultivating theſe annual flowers is this: Dig with a trowel, at proper diſtances, ſmall patches of about eight or nine inches over, breaking the earth very fine, and laying the ſurface even. When the ground is thus prepared, draw a little of the earth off the top to one ſide, ſow the ſeeds thin, and cover them with the earth that was drawn off; the ſeeds ſhould be covered about half an inch deep; but the larger, as the ſweet peas, &c. near an inch.

When the plants appear, let them be judiciouſly thinned, by taking away the weaker and leſs promiſing plants, that the remainder may have proper room to grow and flouriſh.

Tranſplant Flowering Shrubs.

If the weather be mild and open, you may at any time this month, ſafely tranſplant moſt ſorts of flowering ſhrubs, particularly the gelder-roſe, ſyringas, laburnum, lilacs, honey-ſuckles, roſes, ſpiræas, althæ-frutex, hypericum-frutex, Perſian-lilac, double-bloſſom cherry, double flowering-peach, almonds, flowering raſpberries, double bramble, cornelian cherry, and double hawthorn. Bladder-ſena, ſcorpion-ſena, privet, Spaniſh-broom, jaſmines, ſumach, cytiſuſes, acacias, and many other ſorts of hardy plants, may be now tranſplanted.

Tranſplant hardy Fibrous-rooted Flowering Plants.

Moſt of the fibrous-rooted flowering plants, particularly the polyanthuſes, primroſes, London-pride, violets, double-daiſies, double-camomile, thrift, gentianella, hepaticas, ſaxifrage, &c. may be removed to the proper ſituations.

You may alſo now remove roſe-campion, rockets, campanula, catchfly, ſcarlet-lychnis, double-feverfew, batchelors-button, ſweet-williams, columbines, Canterbury-bells, monkſhead, greek-valerian, tree-primroſe, fox-glove, golden-rod, perennial aſters, perennial ſun-flower, holly-hocks, French honey-ſuckles, and ſeveral others of that kind.

But you ſhould remember in planting the above, or indeed any other flowering plants, to mix them in ſuch a manner, that, during the flowering ſeaſon, there may be both a variety of colours, and a regular ſucceſſion of flowers in the different parts of the garden where they are planted.

Tranſplant Carnation Plants.

The choiceſt carnation plants may, about the latter end of the month, be removed into the pots where they are intended to blow, provided the weather be mild and open.

Let the pots be filled with rich light earth, then take up the plants, with as much earth as will readily hang about their roots. Set a ſingle plant in the middle of each pot, and cloſe the earth well about the body of the plants, giving them immediately a moderate watering, by which the plants will be properly ſettled in their places.

You muſt remember to place the pots, as ſoon as the flowers are planted, in a ſituation properly defended from the cold winds.

Tranſplant Evergreens.

Moſt of the hardy kinds of evergreen-ſhrubs and trees, particularly phillyreas, yews, evergreen-oaks, junipers, hollies, firs, cypreſs, cedars, lauriſtinus, pyracunthas, arbutus, &c. may be tranſplanted any time this month when the weather is mild.

Care ſhould be taken to diſpoſe the moſt curious ſorts of flowering-ſhrubs and plants in ſuch a manner, that they may be eaſily ſeen from the walk or lawn near which they are planted. You ſhould alſo be careful not to plant them too cloſe together, nor ſuffer them, as they grow up, to interfere with one another; becauſe great part of the pleaſure of ſeeing theſe ſhrubs

to

to advantage, will, if they ſtand too cloſe together, be deſtroyed.

Tranſplant Box.

If box be wanted for edgings, borders, or to ſupply gaps in edgings formerly made, it may be ſafely planted, in mild weather, any time this month; it will take root readily, and there is no fear of ſucceſs.

Dreſs Auricula Plants.

The choiceſt ſorts of auricula plants in pots muſt now be treated with more than ordinary care, as their flower-buds will ſoon begin to appear; the plants muſt therefore be carefully defended from froſt and cold heavy rains, by covering them with canvas, mats, or glaſſes. But remember to let them be entirely uncovered every mild and dry day.

They muſt alſo be carefully dreſſed; and if ſome freſh earth were not added laſt month, let it be done now, and the ſooner the better.

Tulips, Hyacinths, &c.

Let the beds of tulips, hyacinths, anemonies, and ranunculuſes, be carefully defended from froſts and heavy rains; and thoſe in which the choiceſt ſorts are planted, be now, unleſs done before, arched over with hoops, and covered with mats or canvas, in froſty and extreme wet weather.

Prune Flowering Shrubs.

You muſt now finiſh your work of pruning flowering ſhrubs and evergreens.

Obſerve, in doing this work, to cut all the dead wood, and either to ſhorten or cut off cloſe all ſtraggling irregular branches, and thoſe which interfere with other ſhrubs; for every ſhrub ſhows itſelf to the greateſt advantage, when it is clear of any other.

When the pruning is finiſhed, and the cuttings cleared away, let the ground be neatly dug between and about the plants, obſerving to take off all ſuckers ariſing from the roots.

Dreſs the Borders, Beds, &c.

All flower-borders and beds in general, ſhould now be thoroughly cleaned from weeds, and every kind of litter. Let therefore the ſurface of the beds and borders be carefully looſened with a hoe in a dry day, and neatly raked. This will give the whole an air of livelineſs, which is always very pleaſing to the eye.

Mow Graſs-Walks, and Lawns.

One neceſſary requiſite in rendering graſs-walks and lawns beautiful is neatneſs. The ſeaſon for mowing them now begins to approach; let them therefore be polled and rolled once or twice every week. A wooden roller is beſt to take up the worm caſts; but when theſe are taken away, the walk ſhould be rolled with an iron or ſtone roller, in order to render the bottom firm, and the ſurface ſmooth and even.

Turf.

You may, any time this month, lay turf, where it is wanted, either to make new, or mend old walks. Obſerve to beat it well, and roll it with a heavy roller now and then, in order to make it firm and even; and it will grow freely with very little trouble.

MARCH.

Work to be done in the KITCHEN-GARDEN in March.

Cucumbers and Melons.

BE very careful to examine frequently the ſtate of your cucumber and melon hot-beds, with regard to the degree of heat; for it muſt be both lively and moderate, to preſerve the plants in a ſtate of free growth. If this be properly regulated, the plants will ſhew a plenty of fruit, which will grow to a handſome ſize.

If you find the heat too faint, let a lining of freſh horſe-dung be applied either to the back or front ſides of the bed; but if the heat be not much declined, a lining on one ſide will be ſufficient at a time; but let the other be lined about ten or twelve days after. Let the linings be eighteen or twenty inches thick, and raiſed about five or ſix inches up the frame. The top muſt be covered with earth about two inches thick, to keep down the ſteam.

Remember to let the plants have freſh air every day, and to raiſe the glaſſes in proportion to the heat of the bed, and the warmneſs of the weather.

Let a bottle or two of water be kept always in the frame, to be in readineſs to refreſh the plants now and then. The beſt time for doing this is from ten to two o'clock in a mild ſunny day; but let it always be done moderately.

The glaſſes ſhould be covered every night with mats, and uncovered in the morning about an hour and a half after the ſun.

Some ſeeds of cucumbers and melons ſhould be ſown at three different times this month, viz. at the beginning, middle, and latter end, that a continual ſucceſſion of plants may always be in readineſs, either to plant into new beds, or to ſupply the place of ſuch as may fail in others.

At the beginning of this month you ſhould make hot-beds for planting out the cucumber and melon plants that were ſown in January.

It has already been obſerved, that the ſucceſs will, in a great meaſure, depend upon the due preparation of the dung, before it is made into a bed. Let the bed be about three feet high; the dung beaten down well with the fork, when laid on the bed, but not trodden: when the bed is finiſhed, put on the frame and lights, and let it be managed in every reſpect as before directed in the former month. The ſame directions will alſo be ſufficient for managing the plants, whether cucumbers or melons.

If

If dung could not conveniently be procured for making hot-beds for early cucumbers or melons, laſt month; it is not yet too late, provided the bed be made about the beginning of the month: for the fruit from the ſeeds ſown now will be ready to cut by the middle or latter end of May.

The cucumber and melon plants intended to be reared under hand or bell-glaſſes, ſhould be ſown about the middle of this month.

Cauliflowers.

Let thoſe cauliflower plants as have ſtood all the winter in frames or hot borders, be now tranſplanted.

The ground for this purpoſe ſhould be well trenched, and a good quantity of rotten dung buried in the trenches. Then level the ground; and if it be naturally a wet ſoil, raiſe it up in beds about two feet and a half, or three feet broad, and four inches above the level of the ground; but if the ground be moderately dry, it need not be raiſed at all.

Let the moſt promiſing plants be ſet in the beds prepared as above in rows two feet and a half aſunder, allowing the ſame diſtance between plant and plant in the rows.

Draw up ſome of the earth to the ſtems of cauliflower plants, under hand or bell-glaſſes, taking great care that none of the earth fall into their hearts; this will at once ſtrengthen the plants and promote their growth. But remember to give them air by raiſing the glaſſes on props an inch or two in height; and when gentle ſhowers fall, take the glaſſes entirely away; for this will greatly refreſh the plants.

Should there be more than one or two plants under each glaſs, let them be removed the beginning of this month: for never more than two plants at moſt ſhould be ſuffered to grow under one glaſs. And if the glaſſes are ſmall, one only ſhould remain.

Thoſe cauliflower plants which were raiſed from ſeed ſown the laſt month, ſhould now be pricked into a ſlight hot-bed, which will bring them forward amazingly. Let the bed be eighteen inches high, and either covered with a frame, or arched over with hoops. Cover the bed with rich earth ſix inches deep, prick the plants therein at two or three inches apart, and refreſh them with a little water. Every mild day let the glaſſes or other covering be taken off, but the bed kept covered every night.

At the beginning of this month cauliflower ſeed may be ſown on a ſlight hot-bed, where the plants will ſoon come up, and flouriſh.

You may alſo ſow cauliflower ſeeds in a natural bed of rich light earth, provided the ſituation be warm; but the plants, though they will grow freely, will be near a fortnight later than thoſe ſown upon a ſlight hot-bed.

Cabbages.

Cabbage plants of all kinds may be ſet any time this month, but the ſooner it is done the better. They ſhould be planted in good ground, at about two feet and a half diſtance every way.

It muſt however be remembered, that this diſtance is to be underſtood of ſuch plants as are intended to grow to their full ſize; for eighteen or twenty inches will be ſufficient for thoſe which are intended to be cut up young.

The ſeeds of cabbages intended for autumn and winter uſe, may be ſown any time about the middle of the month; obſerving to ſow each ſort ſeparate, and in an open ſpot of ground.

About the middle or latter end of the month, a little red-cabbage ſeed may be ſown, in order to raiſe plants for the winter.

Savoy ſeed, for a principal crop, intended to ſerve the family from about Michaelmas to Chriſtmas, ſhould be ſown, in an open ſituation, about the latter end of the month.

Carrots and Parſneps.

Carrot and parſnep ſeed, if not ſown laſt month, ſhould be ſown at the beginning of this, for a principal crop.

Carrots delight in a deep, warm, light, ſandy ſoil, which ſhould be dug two ſpades deep, that the roots may run down with greater eaſe; for if they meet with any obſtruction, they are very apt to grow forked, and ſhoot out lateral roots, eſpecially where the ground is too much dunged the ſame year the carrots are ſown, which will alſo occaſion their being worm-eaten. When therefore there is a neceſſity for dunging it the ſame year the carrots are ſown, the dung ſhould be well rotted, and thinly ſpread over the ground; and in the digging of it into the ground, great care ſhould be taken to diſperſe it through the different parts, and not to bury it in heaps. When the ground is inclinable to bind, too much care cannot be taken to break and divide the clods; large ſpits therefore ſhould never be taken in digging for carrots; they ſhould be very thin, and the clods well broken.

The ground, when dug, ſhould be laid level and even, otherwiſe, when the ſeeds are ſown, and the ground is raked over, part of the ſeeds will be buried too deep, and others in danger of being drawn up into heaps; by which means the plants in ſome places will come up in bunches, and in others the ground will be naked; both which ſhould be always carefully avoided.

As theſe ſeeds have a great quantity of ſmall forked hairs upon the borders, by which they cloſely adhere, ſo it is very difficult to ſow them even, or prevent their coming up in patches; the ſeeds ſhould therefore be well rubbed with both hands before they are ſown, in order to ſeparate them. A calm day alſo ſhould be choſen to ſow them; for if the wind blows, it will be impoſſible to ſow the ſeeds equal; becauſe, as they are very light, they will be blown into heaps. When the ſeeds are ſown, the ground ſhould be trodden pretty cloſe, to bury them, and then raked ſmooth and level.

When the plants are come up, and have got four leaves, the ground ſhould be hoed with a ſmall hoe three inches wide, cutting down all young weeds, and ſeparating the plants to three or four inches diſtance each way, that they may get ſtrength. When the weeds begin to grow again, the whole ſhould be hoed over a ſecond time, when care ſhould be taken not to leave two carrots cloſe to each other, and alſo to ſeparate them to a greater diſtance, cutting down all weeds, and ſlightly ſtirring the ſurface of the ground in every part, which will at once prevent freſh weeds from ſpringing up, and facilitate the growth of the carrots.

Sowing

Sowing Turneps.

About the middle, or towards the latter end of this month, as the weather is more or leſs favourable, turneps ſhould be ſown in a light ſoil, and open ſituation. They may indeed be ſown at the beginning of the month, if thought neceſſary; but it ſhould be remembered, that thoſe which are ſown ſo early are apt to run to ſeed before they apple, or, at leaſt, before they obtain any conſiderable ſize.

Sow Onions, Leeks, &c.

The ſeeds of onions and leeks intended for the principal crop, ſhould, if not done in February, be ſown the beginning of this month. Let each ſort be ſown on ſeparate beds of rich mellow earth, and raked in evenly, that the plants may come up equally in every part.

If the earth be very light and rich, the ground ſhould, as ſoon as the ſeeds are ſown, be trodden all over, and then well raked, in order that the ſeed may be buried more regularly.

But where the ground is any thing wet and ſtiff, it will not be ſo proper to tread the ſeed in. The ground ſhould therefore be divided into beds of four, five, or ſix feet wide, with alleys between them; and in theſe alleys the gardener ſhould ſtand to ſow the ſeed, and afterwards to rake it into the ground. Some, for the more certainty of burying the ſeed, throw a little of the earth in the alleys over it, and then lightly rake the whole.

Sow Raddiſhes.

Let ſome raddiſhes be ſown at three different times this month; viz. at the beginning, the middle, and the end, that there may not be wanting a freſh ſucceſſion of young raddiſhes for the table. The ſpot where the ſeed is ſown at this ſeaſon ſhould be open, the ſoil good, and ſomewhat moiſt.

The crops of early raddiſhes ſhould now be thinned where the plants ſtand too cloſe together, by pulling up the worſt, and leaving the beſt plants, at about two or three inches diſtance. At the ſame time the bed ſhould be cleared from weeds.

Theſe early crops ſhould alſo be frequently watered in dry weather; otherwiſe they will grow but poorly, and, at the ſame time, the roots be hot and ſticky.

Sow Spinnage.

About once every fortnight ſome ſpinnage ſeed ſhould be ſown, that there may be a regular ſupply for the table; for one ſowing will not continue above a fortnight before it will run to ſeed. The ſeed ſhould be of the round-leaved kind, ſown thin in an open ſpot, and raked in equally.

The plants of the early crop of ſpring ſpinage ſhould now be thinned, ſo that the plants may be five or ſix inches diſtance from one another.

The crop of winter ſpinnage ſhould be kept clear from weeds, and the earth between the plants ſtirred with a hoe.

Sow Lettuce.

Lettuce-ſeed of different kinds ſhould be ſown about the beginning, middle, and latter end of the month, that there may be a conſtant ſupply for the table.

Let the ſeeds be ſown in an open ſpot of ground, a rich ſoil, and the earth well broken. Sow the ſeeds evenly on the ſurface, and rake them in lightly, taking care to lay the ſurface ſmooth and level.

Thin thoſe lettuce plants which have ſtood the winter in warm beds or borders, where they ſtand too cloſe. But remember to do this regularly, drawing out the weaker and letting the ſtronger plants remain, at about ten or twelve inches from one another. At the ſame time looſen the earth between the plants with a hoe, and clear away all the weeds and litter from the beds and borders.

The plants drawn out ſhould be planted in an open ſpot of rich earth, at about twelve inches from one another.

Sow Aſparagus.

Let the ſeeds of aſparagus be ſown this month, either to make new plantations the following year, or for raiſing beds of that vegetable immediately from the ſeed.

You ſhould be very careful to procure good ſeeds of aſparagus, as the ſucceſs of the whole plantation will greatly depend upon that particular. In order to this, a ſufficient quantity of the faireſt buds ſhould be marked early in the ſpring, and permitted to run up for ſeed; for thoſe which run up after the ſeaſon for cutting the aſparagus is over, are generally ſo backward as not to ripen their ſeeds unleſs the ſummer be warm, and the autumn very favourable. In the choice of buds for their ſeed, great regard ſhould be had to their ſize and roundneſs, never leaving any that are inclinable to be flat, or that ſoon grow open-headed; let therefore the roundeſt and cloſeſt-headed be choſen. But as ſeveral of theſe will produce only male flowers, which are barren, a greater number of buds ſhould be left than might be neceſſary, if there could be a certainty of their being all fruitful. When the buds are left, it will be proper to thruſt a ſtake down by each, taking care not to injure the crown of the root. Theſe ſtakes will not only ſerve as marks to diſtinguiſh them from others, when they are all run up, but alſo to faſten the ſhoots to when they have advanced in height, and put out lateral branches; this caution will prevent their being broken by the wind, which otherwiſe frequently happens, before the other ſhoots are permitted to run up; after which there is indeed little danger, as they will then be ſheltered by the other ſtalks.

Towards the latter end of September the berries will be fully ripe, when the ſtalks ſhould be cut down, and the berries ſtripped off into a tub, where they ſhould remain three weeks or a month to ſweat, by which means the outer huſks will be rotten. Then fill the tub with water, and break all the huſks by ſqueezing them between your hands. The huſks will now all ſwim upon the water, and the ſeeds ſink to the bottom; ſo that by pouring the water off gently, the huſks will be carried away with it; and by pouring in freſh water two or three times, and ſtirring the whole about with your hands, the ſeeds will be entirely clean. Let the ſeed be now ſpread upon a mat or cloth, and expoſed to the influence of the ſun and air in fine weather, till it is perfectly dry; when it ſhould be put into a bag, and hung up, in a dry place, for uſe.

The ſeed being thus procured, a plantation of aſparagus may be raiſed immediately from the ſeed; and this is a very good method, though the beds will require a year longer, before any buds can be cut, than thoſe which are planted with roots; but as the roots of aſparagus always ſend forth many long fibres, which run deep into the ground, ſo when the ſeeds are ſown where they are to remain, theſe roots will not be broken or injured, as thoſe muſt be which are tranſplanted; they will therefore ſtrike deeper into the ground, and make much greater progreſs. At the ſame time the fibres will puſh out on every ſide, which will cauſe the crown to be in the center; whereas in tranſplanting, the roots are rendered flat by the ſide of the trench.

The ground where you intend to make aſparagus beds, ſhould be trenched, and a good quantity of rotten dung turned equally at the bottom of each trench. It will be neceſſary to dig the trenches ſo deep, that the dung may be buried fifteen inches below the ſurface of the dug ground. Then level the whole ſpot very exactly, taking away all large ſtones, and divide it into beds four feet wide, with alleys two feet wide between them.

The ground being thus prepared, draw a line acroſs it, and with a dibble make holes at a foot diſtance, and about half an inch deep. Into each of theſe holes drop two or three ſeeds, leſt one of them ſhould miſcarry, and cover the ſeed by ſtriking the earth in upon it. Remove the line a foot further for another row, and proceed in this manner till the whole ſpot is ſown Some time after the plants appear, they muſt be thinned, leaving only two of the ſtrongeſt plants in each hole; and afterwards thinned a ſecond time, leaving only one plant in each hole.

If the ſeed be only intended for raiſing plants for new plantations, or ſupplying deficiencies in others, it ſhould be ſown on a ſpot of rich light earth; and when the plants come up they muſt be kept perfectly free from weeds, by a careful hand-weeding, and now and then refreſhed with water in dry weather.

Planting Aſparagus.

New plantations of aſparagus may be made any time this month when the weather is mild and open.

In order to this the ground muſt be trenched, prepared, and divided into beds, in the manner above directed for raiſing aſparagus from ſeed.

The beds being finiſhed, ſtrain your line, and open four drills with a ſpade from one end of the bed to the other, twelve inches aſunder; obſerving that the two outſide drills be not nearer the ſide than ſix inches; and when you have opened one drill, to plant that before you open another.

Place the plants ten or twelve inches aſunder, and nearly upright againſt the back of the trench or drill, and in ſuch a manner that the crown of the roots may lie between two and three inches below the ſurface of the ground, and be all placed at an equal depth; ſpreading their roots in a regular manner, drawing, at the ſame time, a little earth up againſt them with the hand, in order to fix the plant in due poſition. When one drill is thus planted, draw the earth immediately into the drill over the plants with a rake; and then proceed to open another drill, planting and covering it in the ſame manner; and ſo on till the plantation is finiſhed. When the whole is planted, let the ſurface of the beds be raked ſmooth, and cleared from ſtones; driving into the corner of every bed a firm ſtake, as a mark for the alleys.

The gardeners about London generally ſow a thin crop of onions the firſt year on their new aſparagus beds; nor will this hurt the aſparagus in the leaſt, provided the onions are not ſuffered to grow too near the plants.

A common error has long prevailed, that the dung uſed for manuring the beds, communicates a ſtrong rank taſte to the aſparagus; but this is a great miſtake, the ſweeteſt aſparagus growing upon the richeſt ground, while that growing on poor ground has the rank taſte ſo often complained of. Nor is this to be wondered at, when it is remembered that the ſweetneſs of aſparagus is owing to the quickneſs of its growth, which is always proportioned to the goodneſs of the ſoil, and the warmth of the ſeaſon. Mr. Miller tells us, that in order to prove this he planted two beds of aſparagus upon ground which had been dunged a foot thick; and the beds were every year after dunged extremely well; and the aſparagus produced from theſe beds were much ſweeter than any he could procure, though they were boiled together in the ſame water.

Dreſs Aſparagus Beds.

About the middle of the month fork up your aſparagus beds; taking particular care that the fork does not reach the crowns of the roots.

Some time after the beds ſhould be raked even; but remember not to defer it longer than the end of the month, or at fartheſt the firſt week in April; for by that time the buds will begin to advance near the ſurface, and, conſequently, be in danger of being injured by the teeth of the rake.

Planting Artichokes.

In order to make a new plantation of artichokes, let the ſurface of the ground you intend for this purpoſe be ſpread over with rotten dung, and dug in. When the ground is thus prepared, a ſufficient quantity of young ſhoots ſlipped from old roots muſt be procured. Let theſe ſhoots, taken from old ſtocks, be clear, ſound, and not woody, having ſome fibres to their bottom; then with your knife cut off that knobbed woody part which joined them to the ſtock; and if that cuts criſp and tender it is a ſign of their goodneſs, but if tough and ſtringy, throw the ſhoot away as good for nothing. Cut off alſo the large outſide leaves of the plants intended for planting, pretty low, that the middle or heart leaves may be above them.

Your plants being thus prepared, they ſhould, if the weather be dry, or the ſhoots any time taken from the ſtocks, be ſet upright in a tub of water three or four hours, which will greatly refreſh them. This being done draw a line acroſs the ground that the ſhoots may be ſet in a row, and with a meaſure-ſtick plant them at two feet diſtance from each other in the rows, and the rows five feet aſunder, if deſigned for a full crop. The plants ſhould be ſet about four inches deep, and the earth cloſed very faſt to their roots; obſerving, if the ſeaſon grows dry, to water them two or three times a week, till they have taken root, after which they will require none.

Thoſe

Thoſe artichokes which are planted in a moiſt rich ſoil, will always produce the largeſt and beſt fruit, which will be fit for the table in Auguſt and September; ſo that where ſuch a ſpot can be found, it will be proper to make a freſh plantation every ſpring, to ſucceed the old ſtocks, and ſupply the table in autumn. But the roots will not live through the winter in a very moiſt ſoil; ſo that the ſtocks intended to remain to ſupply the table early, and furniſh you with plants, ſhould be in a drier ſituation. You ſhould alſo remember to plant artichokes in an open ſpot of ground, not under the drip of trees; for they will there draw up very tall, and produce only ſmall inſignificant fruit.

Dreſs Plantations of Artichokes.

About the beginning or middle of the month, according to the earlineſs of the ſeaſon, or the forwardneſs of the old artichoke ſtocks, the plantation muſt be dreſſed in the following manner.

Remove with your ſpade all the earth from about the ſtock, down below the part where the young ſhoots are produced, clearing away the earth from between the ſhoots, ſo as to be able to judge both of the goodneſs of each, and their proper poſition upon the ſtock. Then make choice of two of the cleareſt, ſtraiteſt, and moſt promiſing ſhoots produced from the under part of the ſtock; for theſe are far preferable to the ſtrong thick plants which generally grow upon the crown of the roots, theſe having hard woody ſtems, and never produce good fruit. The market gardeners about London call them rogues, from their having very little bottom, and the ſcales of their heads being placed irregularly. When you have made choice of two plants, ſlip off the other ſhoots with your hand, obſerving carefully not to injure the plants you intend to remain for a crop. This being done, draw the earth with your ſpade about the two plants which are left, cloſing it faſt to each of them with your hands, and ſeparating them as far aſunder as they can conveniently be placed without breaking them. At the ſame time crop off the tops of the leaves that hang down with your hands. Then level the ground between the ſtocks, and the whole operation will be finiſhed.

The ſhoots which were ſtripped off will do to form freſh plantations of artichokes, where wanted, in the manner above deſcribed; for there is no other method of increaſing artichokes, than by planting the young ſhoots.

Plant Beans.

Beans of all kinds may be planted at this ſeaſon; let ſome be put into the ground once a fortnight, by which method the table will be conſtantly ſupplied with young beans during the ſeaſon. The white bloſſom bean, as it is a great bearer, will anſwer the purpoſe exceedingly well.

Let the larger ſorts of beans be planted in rows a yard aſunder; but two feet and a half will be ſufficient for the leſſer kinds.

Sow Peas.

All kinds of peas may be ſown any time this month; ſo that if you ſow a few every fortnight, or thereabouts, a conſtant ſupply will be the conſequence. Let drills be drawn for the different kinds of peas, according to the directions given in the foregoing month; ſow them regularly, and cover them with earth about an inch and a half deep.

Let the earth be drawn up to the ſtems of ſuch peas and beans as are now grown to ſome height; this will greatly ſtrengthen the plants, and encourage their growth.

Plant Kidney-Beans.

About the latter end of the month, if the weather be mild and dry, and the ground not too wet, a few kidney-beans may be planted cloſe under ſome warm wall; but without that precaution they will not ſucceed.

In ſuch a warm ſituation let drills be drawn for them, about two feet, or two feet and a half aſunder. Plant the beans in the drills about two or three inches apart, and cover them with earth about an inch deep.

Plant Potatoes.

You may plant potatoes any time this month, but the ſooner you do it the better.

Be careful to procure roots perfectly ſound and of a tolerable ſize for planting. When a ſufficient quantity of theſe is procured, let them be prepared for planting by cutting or quartering them; that is, let each root be cut into two, three, or more pieces, carefully obſerving that each piece be furniſhed with one or two eyes.

When you have thus prepared your roots, let them be planted in rows about a foot and a half or two feet aſunder, and twelve or fifteen inches apart in the rows. They may be planted as you proceed in digging the ground, placing the roots in the trenches, and it would be of great advantage if a little dung were laid over every row of potatoes, and the earth thrown in upon the dung.

Mr. Miller obſerves that many of the roots cut in the above manner often rot, eſpecially if the weather ſhould prove wet, ſoon after they are planted; and therefore recommends the faireſt roots to be planted entire in the rows, inſtead of the ſeparate parts; and to allow them a larger ſpace of ground both between the rows and between the roots. By this method he aſſures us, that the roots will be in general large the following autumn.

It is the practice of ſome gardeners to dig holes about two feet and a half over, and eight inches deep, and to throw into each hole as much rotten dung as will half fill it, laying the dung higheſt in the middle, and then to place the potatoes upon the dung about half a foot aſunder, covering them ſix or ſeven inches deep with the earth that was thrown out of the holes. The holes muſt be at leaſt a yard every way aſunder. By this method fine crops of very large potatoes are procured.

Plant Jeruſalem Artichokes.

Theſe roots will thrive in almoſt any ſoil; but when they have once taken root, it will be difficult to clear the ground of them, for the leaſt bit will grow.

They may be planted any time this month, in rows two feet aſunder, and about fifteen inches apart in the rows.

Plant Mint.

New plantations of mint may be made this month, with little trouble.

It is propagated either by ſlips or parting the roots; but the former is generally practiſed. The method is this:

About the latter end of this month ſlip off and draw up with all their roots, a proper quantity of the beſt of the young plants, from ſuch old beds of mint as are well ſtocked with them. The beſt manner of doing this is to draw up the young plants gently with the help of your knife, ſeparating them carefully as they riſe from the old roots. If this be properly performed, every plant will riſe with tolerable good roots.

When a ſufficient quantity of theſe plants are procured, let them be ſet in rows ſix inches aſunder, and the ſame diſtance apart in the rows. As ſoon as they are planted, let a tolerable watering be given them to ſettle the earth about their roots.

If you intend to form a plantation of mint by roots, a ſufficient quantity of them muſt be procured, and parted in a proper manner. Then draw drills with a hoe ſix inches aſunder, place the roots about ſix inches apart in the drills, covering them with about an inch deep of earth, and rake the whole ſpot of ground. This method will ſucceed beſt if done the beginning of this month, or in October or November.

Plant Cives.

Cives may be planted any time this month, in the following manner: Let a ſufficient quantity of ſlips from old roots be procured, and planted in beds about eight inches from one another.

Plant Garlic, Shallots, &c.

Both garlic and ſhallots may now be planted in the ſame manner as directed laſt month; but the ſooner it is done the better.

Plant Onions.

Such of the dry onions as begin to ſhoot in the houſe, may be now planted in a ſmall ſpot in the garden: they will ſerve to pull up for ſcallions.

Plant Roſemary, Rue, Southernwood, &c.

Any time this month you may plant the ſlips or cuttings of roſemary, rue, ſouthernwood, or lavender. A ſhady border ſhould be choſe for this purpoſe, and the ſlips or cuttings planted ſix inches apart. They will take root freely, if watered in dry weather. When they are well rooted, and have acquired a conſiderable degree of ſtrength, they may be tranſplanted into a more open ſituation.

If the plantation be made with cuttings, let theſe be taken from ſhoots produced the laſt year. They ſhould be from five or ſix to eight or nine inches long, and each cutting ſet about two-thirds of its length into the earth.

But whenever you can procure ſlips, or ſuckers, that riſe immediately from the roots of older plants, theſe ſhould be choſen; becauſe they are often well furniſhed with roots.

Plant Sage, Hyſſop, Thyme, Penny-royal, &c.

The ſlips or cuttings of ſage, hyſſop, thyme, &c. may be planted any time this month.

Theſe cuttings ſhould be taken from the laſt year's ſhoots, and about five, ſix, or ſeven inches long; but as there are ſometimes ſlips, or ſuckers, ariſing from the bottoms of the old plants, theſe ſhould be choſen, eſpecially if they are furniſhed with roots.

Let theſe, whether cuttings or ſuckers, be planted in a ſhady border, where they will ſoon take root, and, in three or four months, become good plants, provided they are watered in dry weather. When they are well rooted, they may be taken up, and planted at proper diſtances, in beds of rich earth.

Sow Purſlane.

If purſlane be required early, it ſhould be ſown on a hot-bed the beginning of this month. Eighteen inches deep of dung will be ſufficient for this purpoſe: put the frame on, and cover the bed with earth five or ſix inches thick. Sow the ſeed on the ſurface, and cover it about a quarter of an inch with light earth.

About the end of the month, if the weather be warm, the ſeed may be ſown in a natural bed of rich earth.

Sow Parſley, Chervil, &c.

Parſley, chervil, and coriander ſeeds may be ſown any time this month. In order to which, let ſome ſhallow drills be drawn eight or nine inches aſunder, and in theſe the ſeeds ſown, each ſort ſeparate. Cover the ſeeds when ſown about half an inch deep with earth.

You may ſow parſley, in ſingle drills, at the edge of the quarters, or borders of the garden: it will make a uſeful, and, at the ſame time, a neat edging, if not ſuffered to grow too rank.

Sow Celery.

If you omitted to ſow celery laſt month, let it be ſown the beginning of this, for an early crop; more of the ſeed may be ſown about the middle, or latter end, of the month, for a principal crop. The ſeed ſown at the beginning of the month ſhould have a warm ſpot of rich earth. Let the ſeed be ſown on the ſurface, and either covered about a quarter of an inch with light earth, or raked in lightly with an even hand. Remember to ſprinkle the bed with water frequently in dry weather.

Sow Fennel, Dill, Savory, Hyſſop, Thyme, &c.

The ſeeds of fennel, dill, burnet, ſorrel, marygold, &c. ſhould be ſown the beginning of this month, if omitted in February.

With regard to hyſſop, thyme, ſavory, and ſweet-marjoram, they will ſucceed, if ſown any time this moth.

All theſe ſeeds ſhould be ſown ſeparately, in ſpots of light earth, and raked in with an even hand.

Sow ſmall Salleting.

All kinds of ſmall ſalleting, ſuch as creſſes, muſtard, raddiſh, rape, and turnep, ſhould be ſown once a week, at leaſt, in a warm border. Let the ſeeds be ſown, each ſort ſeparate, in ſhallow drills, three inches aſunder, and covered lightly with earth.

Sow Capſicum.

The ſeeds of capſicum ſhould be ſown in a hot-bed, about the middle, or towards the latter end of the month; when the plants appear, let them have a large portion of free air, and frequent ſprinklings of water. When they are fit to remove, which will be about the latter end of May, they muſt be tranſplanted into beds of rich earth, in the common ground.

Sow

Sow Cardoons.

About the middle of this month you may ſow cardoons in a bed of light rich earth, in an open ſituation. The ſeed muſt be ſown thin, and the bed watered frequently in dry weather.

Sow Naſturtiums.

Naſturtiums require a dry ſoil, and open ſituation; in ſuch a ſpot therefore let drills about an inch deep, and two feet diſtance, be drawn. Let the ſeeds be placed in theſe drills about two or three inches apart, and covered with earth the depth of the drill. When the plants, which are of the climbing kind, riſe and begin to run, ſet ſticks, as you do for peas, to ſupport them.

Sow Hamburg Parſley.

The ſeeds of Hamburg, or large-rooted parſley may now be ſown, if omitted the foregoing month. Let the ſeed be ſown thin, and equally, on beds of rich earth, in an open ſituation, and raked in with an even hand. When the plants are up, and have acquired a little ſtrength, they muſt be thinned to ſix inches diſtance, that the roots may have room to ſwell; for the root only of this plant is eaten.

Sow Scorzonera, Salſafy, and Skirrets.

The ſeeds of ſcorzonera, ſalſafy, and ſkirrets, may be ſown any time this month. But remember to ſow each ſort on ſeparate beds, in an open ſituation, and to rake the ſeed in lightly.

The NURSERY.

Sow the Seeds of hardy Exotics.

The ſeeds of many ſorts of hardy exotic trees and ſhrubs may be ſown this month; ſuch as the tulip-tree, larch-tree, and plane-tree; the ſaſſafras, arbor-judæ, Virginia dogwood, American cypreſs, Virginia walnut, acacias, and many others of the like kind.

The method of ſowing the ſeeds of theſe hardy kinds, many ſorts of which will grow freely, and with very little trouble, is this:

Dig a ſpot for them where the ground is dry, of a looſe texture, and in a ſituation not too much expoſed. Let the earth be well broken, and the ſurface made very level.

When this is done, let the piece be divided into beds three feet and a half wide, and ſub-divided into as many parts as you intend to ſow different kinds of ſeed.

Let each ſeed be ſown, or planted, according to the kinds and ſizes of the different ſeeds, in its ſeparate ſpot.

Cover the ſeeds with fine light earth, taking care that each ſort, according to its ſize, be covered a proper depth; ſome half an inch, ſome an inch, and others an inch and a half, according to the ſize of the ſeeds, fruits, or nuts.

The beds muſt be frequently ſprinkled with water, in dry weather; and, when the ſun is hot, a little ſhading with mats will be of ſervice.

Sow the ſeeds of the Cedar of Lebanus, Pines, Firs, and other hardy Evr-Green Trees and Shrubs.

This is the proper ſeaſon for ſowing the ſeeds of the cedar of Lebanus, pines, firs, cypreſs, juniper, and the like.

Let a ſmall ſpot of light earth be dug for theſe ſeeds, divided into ſmall beds, the ſeed ſown thereon, each ſort by itſelf, and covered with rich earth about half an inch thick.

You ſhould remember to water and ſhade your plants in hot dry weather, eſpecially while the plants are young, for then both will be of moſt ſervice.

This is alſo the ſeaſon for ſowing the ſeeds of the arbutus, or ſtrawberry-tree; but there will be more certainty of ſucceſs, if it be ſown on a hot-bed. The method is this:

Fill ſome ſmall pots with light freſh earth, ſow the ſeed therein, covering it about half an inch, and plunge the pots up to their rims in a hot-bed.

Sprinkle the ſurface of the earth in the pots frequently with water; and when the plants appear, give them a large quantity of freſh air.

Theſe ſeeds will indeed grow, if ſown in a bed of natural earth; but the growth of the plants will be much leſs in the ſame time, and the ſucceſs more uncertain.

You may now alſo ſow the acorns of ever-green oaks, the ſeeds of the phillyrea, bay, and other ever-greens.

All theſe ſeeds ſhould be ſown in light earth, the acorns covered about an inch deep, but the other ſeeds only half an inch.

Propagating Exotic Trees, &c. from Cuttings.

Exotic trees and ſhrubs may, at this ſeaſon, be propagated from cuttings. The method is this:

Dig a ſpot for them where the ground is ſomewhat moiſt, and not ſtiff; break the earth well with the ſpade, and rake it ſmooth. This being done, divide the ſpot into as many parts as you have different ſorts of plants to propagate.

Let the cutting be taken with a ſharp knife from the trees you intend to increaſe, and from the ſhoots of the laſt ſummer. They ſhould be from ſix to ten inches long, and planted in rows, each cutting being planted half way into the ground. Cloſe the earth well about them, water them in dry weather, and keep the whole ſpot clear from weeds.

Tranſplant Ever-greens and Exotic Trees.

This is a proper ſeaſon for tranſplanting moſt kinds of ever-green trees and ſhrubs from the ſeed-beds, or other places where they ſtand too cloſe together; particularly the ever-green-oak, phillyrea, alaturnus, pyracantha, lauriſtinus, Portugal laurel, arbutus, cytiſus, hollies, and yews. Alſo cedars and cypreſſes, pines, firs, and junipers, may now be tranſplanted with ſafety.

Exotic trees, or ſhrubs, may alſo be removed at this ſeaſon.

Tranſplant Flowering Shrubs.

You may now remove moſt kinds of the hardy flowering ſhrubs.

But you ſhould remember to perform this operation in calm cloudy weather, when either the more tender kinds,

or the ever green plants, are to be removed; for upon this particular, and the expedition with which they are planted after they are taken up, the ſucceſs of the operation will, in a great meaſure, depend.

Be careful in planting them to break the earth perfectly fine, and ſee that it falls in properly between and about their roots.

As ſoon as they are planted, let them be well watered, and the waterings occaſionally repeated in dry weather.

You ſhould alſo cover the ſurface of the ground with mulch, or long litter, in order to prevent the ſun and wind from drying the earth too much about their roots.

Let firm ſtakes be fixed in the ground, and the ſtems of thoſe plants which require ſupport, be faſtened to them.

Plant Vines.

This is a proper ſeaſon for propagating vines from cuttings.

The cuttings ſhould be taken from ſhoots of the laſt year's growth, ſhortened to ten or twelve inches; and, if poſſible, have an inch or two of the branch from whence the ſhoot was taken, at the extremity of each cutting.

Let the cuttings be planted in a ſlanting direction, and ſo deep that one eye only may be ſeen above the ſurface.

By this method moſt of the cuttings will ſucceed; they will take root freely, and even produce tolerable ſhoots the ſame ſeaſon.

Water them moderately in dry weather, and keep the ground perfectly free from weeds.

Let theſe cuttings be planted in the place where they are to remain; for they never ſucceed ſo well after tranſplanting.

Grafting.

Apples, pears, plums, cherries, &c. may be grafted any time this month.

You may cut off the ſtocks which are to be grafted for ſtandard-trees to what height you pleaſe.

The ſame method is to be purſued in performing the operation of grafting, as mentioned in the work of the nurſery laſt month.

Dreſs the Beds of Seedling Trees and Shrubs.

Look attentively over the ſeed-beds of young trees and ſhrubs; and where any weeds appear, let them be carefully picked out by the hand; for if they are ſuffered to continue, their roots will mix with thoſe of the young plants, and conſequently render it difficult to remove the one without injuring the other.

Water the Seed-beds of young Trees and Shrubs.

You muſt remember to refreſh the ſeed-beds of young trees and ſhrubs with water now and then in dry weather; a little at a time will be ſufficient for the purpoſe. This will be of the utmoſt ſervice to them, as you will ſoon perceive by their growth.

The FRUIT-GARDEN.

Plant Fruit-trees.

From the beginning to about the twentieth of this month, all kinds of fruit-trees may be planted with ſucceſs. And in moiſt ſoils there will be little danger of their growing, if planted at the latter end of the month; but the ſooner it is done the better.

The trees that are now planted will take root in a ſhort time; and, with the aſſiſtance of a little water in dry weather, ſhoot freely.

Obſerve the directions given in the former month with regard to the diſtances at which fruit-trees, either for walls, eſpaliers, or ſtandards, ought to be planted.

Let a large hole be dug for each tree, and when carried to the depth intended, let the mould at the bottom be well looſened.

When the tree is ready for planting let all the ragged roots, and thoſe which are bruiſed, be cut off; and the ends of all the reſt be trimmed.

As ſoon as this is done, place the tree in the hole, break the earth well, and throw it in equally about the roots. When all is in tread the ſurface round the tree.

Remember to ſecure all new-planted fruit-trees againſt the violence of the wind; ſtakes ſhould be fixed in the ground for the ſupport of ſtandard-trees, and thoſe planted againſt walls or eſpaliers be faſtened thereto.

Plant Fig-trees.

This is a very proper ſeaſon for planting fig-trees; for they will now take root in a very ſhort time.

It is neceſſary to obſerve that fig-trees are propagated either from layers, or ſuckers ariſing from the roots of old trees.

When therefore it is intended to plant thoſe trees, let a ſufficient number of good ſuckers of a moderate growth, and ſuch as are firm or well ripened, be procured at the beginning of this month, and planted where they are to remain.

But fig-trees raiſed from layers made from the branches, are preferable to thoſe from ſuckers; becauſe the latter are more apt to run to wood than the former. The time for laying down the branches in order to raiſe young trees, is either in this month or in October or November: but remember to cover them with long litter in hard froſts. In one year's time the layers will be ſufficiently rooted, when they ſhould be ſeparated from the old ſtock, and planted where they are to remain.

Remember to make your layers from branches of fruitful trees; for thoſe which are made from the ſuckers, or ſhoots produced from old ſtools, have very ſoft branches, full of ſap, and therefore are in danger of ſuffering from the froſt. They will alſo run greatly into wood, and not be very fruitful. Let the ſhoots therefore that are laid down be woody, compact, and well ripened; not young ſhoots full of ſap, and whoſe veſſels are, conſequently, large and open.

If fig-trees are to be planted againſt walls, or pales, they ſhould not be ſet nearer to each other than twenty feet.

Pruning Fig-trees.

This is the beſt ſeaſon of the year for pruning fig-trees; for if they are pruned at the latter end of autumn, as is often practiſed, many of the young bearing ſhoots, which are tender, are very liable to be killed by the ſevere froſts; but if the pruning be omitted till this month, when the froſts are over, there is great reaſon to hope, that though ſome of the bearing branches may have periſhed by the ſeverity of the weather, enough

enough of them will have eſcaped the froſt, to furniſh the wall.

Obſerve in pruning fig-trees, to leave a ſufficient ſupply of the laſt ſummer's wood, from the bottom to the extremity, every way, and in every part where there is proper room to train the ſhoots, ſo that the tree may be equally furniſhed with them at moderate diſtances; for theſe bear the figs the enſuing ſeaſon.

Remember to train in every year ſome young ſhoots at, or near the bottom, that there may be a proper ſupply of young branches, coming out regularly one after another, to ſupply the places of old naked branches, which will appear every ſeaſon, in ſome part or other of the tree. At the ſame time let all the old branches which are deſtitute of young wood be cut out; by which means there will be ſufficient room to train the bearing branches neatly, and at proper diſtances; for they ſhould neither be left, nor laid in too cloſe.

You muſt never ſhorten, or top, the young branches of fig-trees; they muſt be left at full length; for by ſhortening the branches you will not only cut away the part where the fruit would otherwiſe have appeared, but alſo occaſion the branches to run greatly to wood, and never produce half a crop of fruit.

Obſerve to nail every branch ſtrait and cloſe to the wall, and at about ſeven or eight inches from one another.

Prune Apricot, Peach, and Nectarine-trees.

All the apricot, peach, and nectarine-trees that were not pruned laſt month, muſt be now pruned and nailed, and the ſooner the better; for the whole muſt be finiſhed before the middle of the month.

The greateſt care ſhould now be taken in pruning, and eſpecially in the nailing of theſe trees; becauſe as the buds are now conſiderably ſwelled for bloom, the leaſt touch will rub them off.

The ſame method is to be obſerved in pruning trees now as in the former months.

Guard the Apricot, Peach, and Nectarine-trees from Froſt.

You ſhould be careful to defend the choiceſt kinds of your apricot, peach, and nectarine trees, when in bloſſom, from froſts, which often happen at this time of the year.

In order to this, mats, of the larger kind, ſhould be nailed from one end of the wall to the other, letting them hang down over the trees. The lower ends of the mats ſhould alſo be faſtened down, to prevent their being blown to and fro by the wind, which would inevitably beat off many of the bloſſoms.

But whenever the weather is mild, the mats ſhould be taken away; for the bloſſoms require this kind of ſhelter in ſharp froſts only.

Prune Cherries, Plums, Apples, Pears, &c.

You muſt now forward the pruning of cherries, plums, apples, pears, and all other kind of fruit-trees, whether ſtandards or planted againſt walls or eſpaliers, which could not be pruned in the foregoing month, with all the diſpatch poſſible: let the whole be finiſhed by the middle of the month at fartheſt.

Pruning and ordering young Apricot, Peach and Nectarine-trees.

This is the proper ſeaſon for heading down young apricot, peach, and nectarine-trees, which have been planted ſince Michaelmas laſt, with their firſt ſhoots from budding at full length.

This operation ſhould be performed juſt as the trees begin to puſh; you will therefore do well to watch the proper opportunity, and let their heads be then ſhortened; for this will prove of the utmoſt advantage to the young trees.

The head ſhould be cut down to the third or fourth eye from the bottom; and if there are two ſhoots from the ſame ſtock, let both be ſhortened in the above manner.

By this method the trees will produce ſome ſtrong ſhoots near the ground, which will enable you to furniſh equally every part of the wall with branches.

On the contrary, by omitting to head the trees, they would run up with a head like a ſtandard-tree, and hardly furniſh a ſingle branch within two or three feet of the ground; and, conſequently, that part of the wall would be rendered wholly uſeleſs.

With regard to thoſe young apricot-trees that were headed now a year ago, and each produced three or four ſhoots the laſt ſummer, you ſhould now ſhorten theſe ſhoots to ſuch lengths as may encourage each ſhoot to produce two or three new ones the ſame ſeaſon. The method is this:

Let each ſhoot be ſhortened to about one half of its original length; that is, ſuch as are twenty inches long, ſhould be about ten or eleven inches; and ſuch as are fifteen inches, or thereabouts, in length, ſhould be ſhortened to eight or nine; and ſo in proportion to the different lengths of the ſhoots.

Prune young Apple, Pear, Plum, and Cherry-trees.

Let the heads of young dwarf-apple, pear, plum, and cherry-trees, lately planted againſt walls or eſpaliers, be now pruned down, in order to induce them to put out ſome good ſhoots, near the ground, to furniſh that part of the wall or eſpalier.

If the heads of theſe trees are only of one year's growth from the bud or graft, let them be ſhortened to three or four eyes, obſerving what was mentioned before, namely, to do it juſt when the buds begin to break.

If they are two years from the bud or graft, and the firſt ſhoots were, laſt ſpring, cut down as above, let the ſhoots which were produced from them laſt ſummer, be now alſo ſhortened to ſix or ſeven inches.

You muſt obſerve the ſame rule with regard to theſe trees, as mentioned above for the apricots and peaches; for it is by a judicious ſhortening the firſt and ſecond year's ſhoots from the budding and grafting, that the whole ſucceſs depends with regard to the forming at once a uſeful and a beautiful tree.

When a young wall or eſpalier tree is once well furniſhed with branches near the ground, theſe will eaſily ſupply you with more in their turn, to cover the wall or eſpalier upwards.

But in the common courſe of pruning apple, pear, plum, and cherry trees, their ſhoots or branches ſhould not be ſhortened; for after the young trees are furniſhed with a proper ſupply of branches at the bottom, their ſhoots muſt then be trained to the wall at length,

ſhortening

ſhortening only a particular ſhoot at places where more wood may be required to cover the part.

Prune and dreſs Gooſeberries and Currants.

If there be any of your gooſeberry or currant-buſhes yet remaining unpruned, let the work be done at the the beginning of the month.

Remember to keep the branches thin, and the middle of the tree open and clear of wood, ſo as to admit the ſun and air freely; for by that means the fruit will be larger, and much finer taſted.

At the ſame time let the ground be dug between the gooſeberry and currant-trees, where it has been omitted in the former months. For the looſening of the ground about theſe ſhrubs is of the utmoſt advantage to them, and at no time more uſeful than at preſent, when they are juſt beginning to ſhoot.

Prune and dreſs Raſpberries.

Let all the pruning of raſpberries be now finiſhed; obſerving to cut out all the dead wood; and where the live wood ſtands too thick, let part of it be taken away, as mentioned in the former month, ſhortening at the ſame time the ſhoots that are left.

Remember alſo to dig the ground between the rows of raſpberries, where it was not done before; for this will at once ſtrengthen the ſhoots, and give the bed a clean and neat appearance.

You may ſtill make plantations of raſpberries, provided the whole be finiſhed by the middle of the month. The plants will take root ſoon after they are ſet, and grow freely, provided they are now and then refreſhed with water in dry weather.

Remember in planting raſpberries to make uſe of the young ſhoots produced from the old roots laſt year; chooſing thoſe whoſe roots are well furniſhed with fibres, and rejecting thoſe whoſe extremities are naked and ſticky. The inſtructions for planting theſe ſhoots given in the former month, will be ſufficient for the purpoſe, and therefore need not be repeated.

Dreſs Fruit-tree Borders.

Let all the fruit-tree borders be dug at the beginning of the month, if it was not done the preceding. This will be of great ſervice to the trees, deſtroy the weeds, and give the borders when raked, a neat and pleaſing appearance.

At the ſame time the borders which were dug the preceding month, ſhould be ſtirred with a hoe, and then raked very ſmooth. This will greatly retard the growth of the young weeds, and make the whole appear neat and decent.

Dreſs Strawberries.

If any of your ſtrawberry beds ſtill remain undreſſed, let the work be done as faſt as poſſible; for the plants will now begin to puſh apace.

Clear the beds from weeds, and the plants from ſtrings and other litter; at the ſame time let ſome of the plants be taken away, wherever they are found to ſtand too thick.

The beſt method of keeping theſe plants is in ſingle trenches as it were, ſeparate from one another, ſo that there may be room to dig round them with a narrow ſpade or a trowel.

As ſoon as you have cleared the beds from litter, looſen the earth between the plants; and if you add a little freſh earth to the beds it will ſtrengthen the plants, ſo that they will flower much ſtronger, and produce larger fruit.

Plant Vines.

Cuttings of vines may be planted any time this month; they will take root freely.

Let the cuttings be planted ſomewhat ſlanting, and ſo deep, that one eye only may be above the ground, and that cloſe to the ſurface. And be ſure to plant them where they are to remain.

The cuttings muſt be ſhoots of the laſt year, and ſhortened to about twelve inches in length: and let each cutting have about an inch of the preceding year's wood at the bottom.

Prune Vines.

If any of your vines ſtill remain unpruned, let it be done as ſoon as poſſible at the beginning of the month; for thoſe vines that are pruned too late ſeldom produce a good crop of grapes.

The Pleasure or Flower-Garden.

Sow tender Annual Flowers.

About the beginning of this month a hot-bed ſhould be made for ſowing tender annual flowers, provided that work was not done in February. They ſhould be made entirely in the ſame manner as directed in the foregoing month; and the ſame kind of ſeeds ſhould be ſown. By good management the plants raiſed at this ſeaſon may be brought to flower ſtrongly and beautifully in July.

Tranſplant tender Annual Flowers.

Let a hot-bed be made about the middle or latter end of this month, in order to prick the tender annual flowers that were ſown in February. Let the bed be about three feet high, and the ſurface even; then ſet on the frame; and when the great heat is over, let it be covered with light, rich, and perfectly dry earth, ſix inches thick.

As ſoon as you perceive the earth is warm, prick the plants therein at three or four inches each way, and give them a gentle ſprinkling of water. Put on the glaſſes, but remember to raiſe them a little every day to let the ſteam eſcape; and ſhade the plants from the ſun till they have taken root.

When the plants have taken root, and begin to puſh, let the glaſſes be raiſed a conſiderable height every day, that they may have a ſufficient quantity of freſh air; and, at the ſame time, remember to give them frequently a gentle ſprinkling of water.

Sow the hardier Kind of Annual Flowers.

In the beginning of this month, a hot-bed ſhould be made for ſowing the ſeeds of the hardier kind of annual flowers.

The bed ſhould be two feet high, made in the uſual manner, and covered with rich earth four or five inches thick.

On this bed you may ſow the ſeeds of China aſter, Indian pink, marvel of Peru, balſam, palma Chriſti, capſicum, mignonette, French and African marygolds, ten-

ten-week ſtocks, chryſanthemum, tree and purple amaranthus, perſicarias, love-apple, ſcabiouſes, convolvulus major, ſtramoniums, and ſeveral others of the like ſorts.

Let the ſeeds be ſown each ſort ſeparate, in ſhallow drills, drawn from the back to the front of the frame, two or three inches aſunder. Cover the ſmaller ſeeds about a quarter, and the larger half an inch. When the plants are come up let them have air by raiſing the glaſſes a conſiderable height every day; and as ſoon as they have gathered a little ſtrength, they muſt be gradually hardened to bear the open air, by taking the lights entirely off every mild day. Remember to refreſh them often with moderate ſprinklings of water. About the middle of next month ſome of them will be fit to prick out, and the remainder in May.

It ſometimes happens that dung cannot be ſpared at this ſeaſon for making a hot-bed: when this is the caſe, the above annual flower ſeeds may be ſown in a warm border, where the earth is rich and light; and if the weather be warm, they will ſucceed extremely well; particularly China aſter, ten-week ſtock, Indian pink, African and French marygolds, chryſanthemum, purple and tree amaranthus, perſicarias, ſcabiouſes, and convolvulus major. Let the ſeeds be ſown thin, each ſort ſeparate, the beds arched over with hoops, and covered with mats every night in bad weather.

By obſerving this management the plants will grow freely, and, if you refreſh them with water in dry weather, they will be fit to plant out in May, or the beginning of June, and flower pretty ſtrongly in autumn.

Sow hardy Annual Flowers.

About the middle of the month you may ſow in the borders, and other parts of the garden, the ſeeds of all ſorts of hardy annual flowers: particularly the large and dwarf annual ſun-flower, oriental mallow, lavatera, larkſpur, flos Adonis, ſweet ſultan, large fleſh-coloured, blue, and yellow lupins, convolulus major, ſweet-ſcented and Tangier peas, and naſturtium. Soon after you may ſow the ſeeds of the Spaniſh nigella, purple and white Candia tuft, Venus looking-laſs, Venus navel-wort, dwarf double poppy, Lobel's-catchfly, dwarf annual lychnis, convolvulus minor, and ſome others.

You ſhould remember in ſowing the above, or any other kinds of annual flower ſeeds, to ſow each ſort ſeparate in patches, in the different borders, in the manner mentioned in February. The plants muſt remain to flower in the places where they are ſown, for they do not ſucceed well after tranſplantation; let them therefore be thinned, where they have riſen too thick. At the ſame time remember to water the ſeeds in dry weather, and alſo the plants after they are come up.

Dreſs the Pots of Annual Flowers.

Clear the plants of the double wall-flowers, double ſtock july-flowers, double ſweet-williams, rockets, roſe campions, catchfly, campanulas, ſcarlet lychnis, &c. that were potted laſt autumn, from decayed leaves. Then take ſome of the earth out of the pots, but do not go ſo deep as to diſplace the roots of the plants. Fill up the pots again with freſh earth, and give them ſome water. By this means their roots will be ſtrengthened, the plants will grow freely, and produce large and beautiful flowers.

Tranſplant Chryſanthemums.

The cuttings of the double chryſanthemums, planted in pots or boxes laſt autumn, ſhould now be removed into ſingle pots, where they are to flower. At the beginning of next month, ſome of them may be planted out in the borders among other flowers, where they will blow ſtrong, and make a handſome appearance.

Nurſe Auricula Plants.

You ſhould be very careful to defend your choice auricula plants from too much wet, cold, winds, and froſt; for either will greatly injure their flower-buds, which are now in great forwardneſs. The pots ſhould therefore be continued under the hoop arches, where the plants may enjoy the benefit of the open air, and, when there is occaſion, be ſufficiently defended by drawing the mats over the hoops.

But, at the ſame time, remember not to debar the plants from a warm and moderate ſhower of rain now and then, if any ſhould happen, for ſuch ſhowers will be of the greateſt ſervice to the plants. Remember alſo, to refreſh them often in dry weather with moderate ſprinklings of water, juſt enough to keep the earth about their roots a little moiſt.

Tranſplant and dreſs Carnations.

You muſt tranſplant all the carnations which were omitted laſt month, at the beginning of this.

Remember to take up the plants with a ball of their own earth about their roots, and place each plant in the middle of each pot, unleſs the pots be large, in which caſe two plants may be ſet in each pot; obſerving to cloſe the earth well about them, and give them a moderate watering to ſettle the earth well about their roots. Let the pots be ſet in ſome proper place where the plants may be defended from cold winds, and let them have moderate waterings frequently in dry weather.

At the ſame time the carnation plants which were removed laſt autumn into the pots where they are to remain, ſhould now have freſh earth given them, by removing the old earth from the tops of the pots, and filling them up with freſh.

In order to this, let the plants be firſt cleared from all dead leaves, then take out as much earth as poſſible out of the pots, without diſturbing the roots of the plants, and fill the pots with freſh mould, laying it cloſe round the plants: after which let them be moderately watered to ſettle the earth. By this means the plants will be ſo greatly ſtrengthened, that they will ſhoot ſtrongly, and produce large and beautiful flowers.

Protect your Tulip, Hyacinth, and Ranunculuſes Beds.

The more curious kinds of tulips, hyacinths, ranunculuſes, and anemonies, muſt be protected from the froſts and cold rains, which frequently happen this month, and which will greatly injure your plants, if they are not well guarded; for their flower-buds are now advancing apace. Let therefore the hoop arches be ſtill continued over the beds, and mats drawn over the hoops every night in heavy rains and froſty weather. By this precaution your flowers will blow large and in great perfection.

But remember to take away the mats when the weather is mild, that the plants may enjoy the benefit of

the freſh air; nor ſhould they be covered in a moderate ſhower of rain, for that will be of great ſervice.

It will not be amiſs, if your beds were at firſt covered with low hoops, to remove them, and place taller in their ſtead, as this will give the plants more air when the mats are drawn over the hoops, and there will be leſs danger of injuring the beds in drawing the mats over the hoops.

Support Hyacinths.

You muſt be now careful to ſupport with ſticks the flower-ſtems of your large double hyacinths, for they now begin to grow apace, and the flowers are too heavy to be ſupported by the ſtock alone. Remember to uſe ſome ſoft tying in faſtening the flower ſtalks to the ſticks, which muſt be fixed in the ground very near the plant.

Sow Perennial Flower Seeds.

Moſt kinds of perennial flower-ſeeds may be ſown this month, particularly carnations, pinks, ſweet-williams, wall-flowers, and all the ſpecies of ſtock july-flowers. You may alſo ſow ſingle roſe campion, catchfly, ſcarlet lychnis, columbines, Greek valerian, ſcabiouſes, and Canterbury-bells.

Sow French Honeyſuckles, Hollyhocks, &c.

The ſeeds of French honeyſuckles, hollyhocks, tree primroſe, campanulas, fox-gloves, and many other ſorts, may be ſown this month. A ſpot of ground in a warm ſituation, but not too cloſe to the walls or fences, ſhould be dug for the above flower ſeeds. Let the ſpot, when dug, be divided into beds of three feet and a half wide, and ſubdivided into as many parts as you intend to ſow different kinds of ſeed, for each kind muſt be ſown ſeparate. Let the ſeeds be ſown thin and covered properly with earth, the larger about half an inch, and the ſmaller about a quarter of an inch deep.

Some gardeners ſow all kinds of perennial flower ſeeds in ſhallow drills, proportioning the depth of each drill to the particular ſort of each ſeed, ſo that they may be covered with their proper depth of earth. Others, after raking the ſurface of the bed ſmooth, draw off equally, with the back of the rake, about a quarter of an inch deep of earth, into the alleys: when this is done they ſow the ſeed, and with the teeth of the rake cover them with the earth before drawn into the alleys. Either of theſe methods may be practiſed with ſucceſs; perhaps the drills are more proper for the larger kinds of ſeed, and the broad caſt for the ſmaller.

But whatever method be uſed in ſowing the ſeeds, you muſt remember to ſprinkle the beds frequently with water in dry weather. Your plants will be fit to prick out in May or June.

Plant Ranunculuſes, Anemonies, &c.

You may now plant ſome ranunculuſes and anemonies; they will blow and make a fine appearance in May and June, when the early ſort are over. But remember to water the plants frequently after they are up, in dry weather, and then they they will flower tolerably ſtrong.

Plant Carnations, Pinks, &c.

This is the ſeaſon for planting in clumps, in the borders, carnations, pinks, ſweet-williams, both double and ſingle; batchelors buttons, double feverfew, golden rod, perennial ſun-flowers, perennial aſters, French-honeyſuckles, columbines, Canterbury-bells, monks-hood, fox-gloves, tree-primroſe, and various other ſorts of the ſame tribe.

All the above plants will take root in a very ſhort time, and flower this ſeaſon, provided they are now and then refreſhed with water in dry weather.

The fibrous-rooted plants may alſo now be planted in the borders at the beginning of this month; ſuch as polyanthuſes, auriculas, double camomile, London-pride, violets, hepaticas, thrift, primroſes, gentianella, and a great variety of others of the ſame kind. Give them a little water when firſt planted, and repeat it at times in dry weather: they will grow freely, and make a fine appearance in bloſſom.

Plant Flowering Shrubs.

In any part of the garden, where flowering-ſhrubs are wanted, they may now be planted; for moſt ſorts will ſucceed: particularly the althæa-frutex, ſpireas, ſyringas, golden-rods, and honey-ſuckles.

Tranſplant Exotic Trees.

The greater part of the hardy exotic flowering-trees or ſhrubs may be tranſplanted any time this month.

Tranſplant Evergreens.

This is a very good ſeaſon for tranſplanting evergreens; for they will take root ſooner now than at any other time of the year: particularly the arbutus, or ſtrawberry-tree, magnolias, bays, pyracanthas, phillyrea, alaturnus, laurel, Portugal laurel, lauriſtinus, evergreen oak, hollies, yews, and a great variety of others.

You may alſo tranſplant pines and firs of all ſorts, cedars of Libanus, cypreſs, junipers, and others of that kind.

Remember in planting evergreens, and indeed ſhrubs of every kind, to let the work be done as expeditious as poſſible, after they are taken up. Let a hole be opened for each ſhrub, large enough to receive the root freely; and when it is deep enough, let the ground be well looſened at the bottom As ſoon as the holes are ready, bring the ſhrubs, and having pruned away the broken or bruiſed roots, place them upright in the hole, break the earth well, and throw it in equally about their roots, and cover them of a proper depth. Let the ſurface of the earth round each ſhrub be made hollow like a baſon, to hold the water when given in dry weather; and let ſome mulch or long litter be laid upon the earth round the tree; this will keep the ground moiſt about the roots.

Let each ſhrub be well watered as ſoon as planted, in order to ſettle the earth about the roots; and, at the ſame time, let ſtakes be fixed in the earth, and ſuch as require ſupport be faſtened thereto.

Be careful to plant your ſhrubs, of whatever kind, at proper diſtances, that when they grow up, they may not crowd one another: for ſhrubs always ſhow themſelves to moſt advantage when they are ſeparate. In a word, there muſt always be room ſufficient left to dig, and hoe and clean the ground between them.

Plant Box edgings.

Box planted at this ſeaſon, will ſoon take root and flouriſh, provided it be properly watered. Where there-

fore

fore any gaps appear in edgings formerly planted, they ſhould be now filled up; for nothing has a worſe appearance than ragged and uneven edgings.

If you like thrift better than box for edgings to borders or flower-beds, it may be planted at the beginning of this month; and it will ſucceed, if watered at proper intervals in dry weather, till it has taken root.

Dig the Borders.

The borders and other parts of the garden that have not already been dug, muſt now be done. Let them alſo be raked ſmooth, which will, at once, give them a neat appearance, and put them in a proper condition for receiving the ſeeds of annual flowers.

Hoe and Rake the Borders.

Thoſe borders which were dug and planted with flowers laſt autumn, muſt have their ſurface looſened with a ſmall hoe, and the earth ſtirred carefully between the plants, taking care of the tender ſhoots of bulbous plants, which are now juſt breaking through the ſurface. A dry day ſhould be choſen for this work, and, as ſoon as the earth is looſened with the hoe, let it be neatly raked, clearing away all the rubbiſh, weeds, and decayed leaves which appear about any of the plants.

This will greatly promote the growth of the flowers, and at the ſame time prevent the firſt growth of ſeed-weeds.

Dig the Clumps in Shrubberies.

Let the ground between the flowering-ſhrubs and evergreens in the clumps and borders, be dug at the beginning of this month, if it was not done the preceding. This will greatly help the plants, and the freſhneſs of the ground will give them an additional beauty.

Gravel Walks.

You muſt now be very careful to keep your gravel walks free from weeds, and all kinds of litter.

If you intend to make any new gravel walks, this is a very proper ſeaſon for doing it.

In order to this, you ſhould chuſe that ſort of gravel which conſiſts of ſmooth even pebbles, mixed with a due quantity of loam; for this will bind exceeding cloſe, and look very beautiful.

But if the only gravel you can procure be looſe or ſandy, you ſhould take one load of ſtrong loam to two or three of gravel, caſt them well together, and turn this mixture over two or three times, that they may be well blended together; if this be mixed in proper proportion it will bind well, and not ſtick to the feet in wet weather.

There are different opinions with regard to the choice of gravel; ſome are for having the gravel as white as poſſible, and in order to make the walks more ſo, they roll them with ſtone rollers, which are often hewn by the maſons, that they may add a whiteneſs to the walks. But this renders it very troubleſome to the eyes, by reflecting the rays of light too ſtrongly. This ſhould therefore be avoided, and ſuch gravel as will be ſmooth, and reflect the leaſt, ſhould be preferred.

With regard to the depth of gravel walks, ſix or eight inches may do well enough; a foot thickneſs will be ſufficient for any; but there ſhould always be a depth of rubbiſh laid under the gravel, eſpecially if the ground be wet; in which caſe there cannot be too much care taken to fill the bottom of the walks with large ſtones, flints, brick rubbiſh, chalk, or any other materials that can eaſily be procured, which will drain off the moiſture from the gravel, and prevent its being poachy in wet weather. If theſe materials cannot be procured to lay at the bottom of the walks, let a bed of heath, or furze, be laid under the gravel to keep it dry. If either heath or furze be laid in green, they will continue a long time, as they will be covered from the air. This bed will prevent the gravel from getting down into the clay, and alſo keep it dry. If theſe precautions are omitted in the firſt laying of gravel upon clay, the water detained by the clay will render the gravel poachy, whenever there is much rain.

Gravel walks are apt to be laid too round, which gives them a narrow appearance, and, at the ſame time, renders them not ſo well to walk upon. A gravel walk of twelve feet wide ſhould have a riſe of about three inches and a half in the middle; that is, the middle ſhould riſe gradually ſo much higher than the ſides.

The ſame proportion ſhould be allowed to every gravel walk; one of twenty-four feet wide ſhould not have above five inches riſe in the middle, and one of ſix feet wide not more than one inch and a quarter; and ſo in proportion for any other breadth.

You muſt alſo, in making gravel walks, have great regard to the level of the ground, ſo as to lay the walks with eaſy deſcents towards the low parts of the ground, that the wet may be drained off eaſily; for when this is omitted, the water will lie upon the walks a conſiderable time after hard rains, which will render them unfit for uſe, eſpecially where the ground is naturally wet or ſtrong: but where the ground is level, and there are no declivities to carry off the water, it will be proper to have ſink-ſtones laid by the ſides of the walks, at convenient diſtances, to carry off the wet; and where the ground is ſo naturally dry, that the water will ſoon ſoak away, the drains, from the ſink-ſtones, may be contrived ſo as to convey the water into ſeſſpools, where it will gradually ſink away; but, in wet land, there ſhould be ſubterraneous drains to convey the water off, either into ponds, ditches, or ſome other place proper to receive it; for where this is not well provided for, the walks can never be either handſome or uſeful.

In order to deſtroy worms, that too often ſpoil the beauty of gravel walks, ſome recommend the watering them well with a ſtrong and bitter infuſion of walnut-tree leaves, eſpecially thoſe parts of the walks moſt annoyed with theſe reptiles. This bitter infuſion will, it is ſaid, as ſoon as it reaches them, force them out on the ſurface, ſo that they may be eaſily gathered up, and taken away. But if, in the firſt laying of the walks, a good bed of lime rubbiſh be placed in the bottom, there will be no need of having recourſe to bitter infuſions; for no worms will ever harbour near lime.

With regard to old gravel walks, you muſt now remember to roll them twice a week, at leaſt, when the weather will permit, by which means they will be firm, and the ſurface ſmooth. They will alſo appear very beautiful, and be agreeable to walk upon.

But where the ſurface is dirty, or over run with weeds or moſs, they muſt be turned; by which means the moſs and weeds will be deſtroyed, and the walks will appear freſh as when firſt made.

Such gravel walks as were broken up, and laid in ridges, at the beginning of winter, ſhould now be levelled down, and put into their proper form.

But ſurely this ridging of gravel walks, in winter, is one of the moſt unneceſſary, and, at the ſame time, the moſt ill-looking contrivances that was ever introduced into a garden. For the walks are thereby rendered entirely uſeleſs, in the winter ſeaſon; nay, even in ſome gardens, rendered incommodious both to the proprietor and the gardener himſelf; and, in all gardens, has a deſolate and confuſed appearance. Nor can any good reaſon be given for this abſurd practice; for it will not prevent the growth of weeds, as pretended, and, at the ſame time, will at once, both deaden the colour, and deſtroy the binding quality of the gravel.

However, where this has been practiſed, let the ridges be levelled down ſome time this month.

In turning gravel walks, remember to tread, rake, and roll them every twenty feet at leaſt. The method is this:

When you have advanced with the turning about twenty feet from the end, let that be trodden all over equally; then ſmooth it off with the back of the rake, and roll it directly. In this manner you are to proceed to the end of the walk; for gravel never binds ſo well as when freſh ſtirred.

Clean Graſs Walks.

Let your graſs walks and lawns be kept perfectly clear of worm-caſts, for theſe ſpoil the graſs, and have an unſightly appearance.

Where-ever, therefore, any of them appear, let them be broken, and ſpread about with a taper and pliable pole, and the graſs be immediately rolled with a wooden roller; by which means the earth thrown up by the worms will be taken away, and you may mow the graſs cloſe and even.

If the weather be mild, the graſs will now begin to grow apace; let therefore your walks, or lawns, be mowed in good time, before the graſs is rank, otherwiſe you will not be able to cut it cloſe enough, to procure a fine and even bottom.

At the ſame time, let all the edges of the walks, or lawns, be neatly cut with a ſharp-edged iron; this will give them a very pleaſing and neat appearance.

Lay Turf.

Any time this month you may make new graſs walks or lawns, for the turf will now grow freely, provided it be laid down as ſoon as it is cut.

Remember to beat it well after it is laid, and to roll it ſufficiently after rain; for by this means the ſurface will be rendered firm and ſmooth.

APRIL.

Work to be done in the KITCHEN-GARDEN in April.

Cucumbers and Melons.

BE careful to examine the heat of your cucumber beds; for if that be deficient, you muſt not expect either a plentiful crop, or fine fruit.

If therefore you perceive the heat of the beds to be faint, let no time be loſt in renewing it, by adding a lining of horſe dung to the ſides of the bed, as directed in the former month. By this addition the heat will be revived, the plants preſerved in a growing ſtate, the fruit will ſet freely, ſwell kindly, and grow to a handſome ſize.

But, at the ſame time, remember to give the plants air every day, by raiſing the ends of the lights at the back part of the frame with props, higher or lower, in proportion to the ſtate of the weather.

A little before ſun-ſet, let mats be thrown over the glaſſes, and removed every morning about an hour after the ſun is up.

Let moderate quantities of water be given the plants occaſionally; the cucumber plants will require it more frequently than the melon; but be ſure not to give them too much at one time.

The melons will alſo require water; but as their fruit will now begin to appear, it muſt be applied very moderately.

Whenever you perceive any decayed or damaged leaves on any part of the plants, whether cucumbers or melons, let them be taken away together with all the decayed flowers.

When the weather is hot, and the beams of the ſun fierce, ſo that you perceive the leaves of the cucumbers or melons to flag, you ſhould be careful to ſhade them either with a mat, or looſe hay thrown over the glaſſes, for two or three hours, while the heat continues.

Make Ridges for Cucumbers and Melons.

About the middle or latter end of this month, according to the warmth of the ſeaſon, you muſt make ridges for ſuch cucumber and melon plants as are to be planted under hand or bell-glaſſes. Theſe ridges are made in the following manner:

Dig a trench about three feet wide, and, if the ſoil be dry, ten inches deep, but if wet, not above three inches, levelling the earth at the bottom of the trench. Then put in your dung, prepared as directed in the preceding months for making hot beds. The dung ſhould be at leaſt two feet thick. If you propoſe to make more than one ridge, the interval between the ridges ſhould be four feet; and theſe ſpaces, or alleys, are, in about a month or five weeks, to be filled with new hot dung, and covered with earth; for this will revive the heat in the ridges, and give freſh vigour to the plants.

When this is done, and the dung in the ridge has a proper degree of heat, cover it with earth about four inches thick round the ſides, raiſing hillocks in the middle of the ridge, three feet and a half aſunder. Set the glaſſes upon the hills, leaving them cloſe down about twenty-four hours, in which time the earth in the hills will be ſufficiently warmed.

Stir up the earth of the hillock with your hand, and make it a little hollow in the middle, in the form of a baſon; in each of which let three or four cucumber.

or two melon plants be ſet, obſerving to ſhade them until they have taken root; after which, you muſt be careful to give them air, by raiſing the glaſſes on the oppoſite ſide to the wind, in proportion to the heat of the weather: but remember that this is to be done only about the middle of the day, till they are able to bear the ſun without flagging, when they ſhould enjoy both freely.

Remember to cover the glaſſes every night with mats, till the latter end of May.

If your plants have not been ſtopped before, remember to do it now. This operation ſhould be performed when they have two, three, or four leaves, by pinching off the top of the plant; by which means each plant will produce two, three, or four ſhoots, or runners: and when theſe runners have three joints, it will be proper to ſtop them alſo, by pinching off the top of each at the third joint, which will cauſe each of theſe runners to put out two, three, or more ſhoots. By this means, the plants will be furniſhed with fruitful runners; for it is from theſe lateral ſhoots we are to expect the fruit; but if the plants were not to be ſtopped as above directed, there would not be above one or two runners from each plant, and theſe perhaps extend a yard in length, without ſhewing a ſingle fruit, eſpecially the cucumber.

When the fruit appears upon the plant, there will alſo appear many male flowers on different parts: theſe may at firſt ſight be diſtinguiſhed; for the female flowers have the young fruit ſituated under them, whereas the male have none; but have three ſtamina in their center, loaded with a golden powder, intended to impregnate the female flowers; and when the plants are expoſed to the open air, the ſoft breezes of wind convey this farina, or male powder, from the male to the female flowers. Under frames the caſe is different: the breezes of air are wanting to convey the farina from the male to the female flowers; and for want of this, many of the fruit drop off, becauſe the flowers were not impregnated. The curious have often obſerved, that the bees which have crept into the frames when the glaſſes have been raiſed to admit the air, have ſupplied the want of theſe gentle breezes of wind, by carrying on their hind legs the farina of the male into the female flowers, and left there a ſufficient quantity of it to impregnate them. Theſe induſtrious inſects have taught the gardeners a method of ſupplying the want of a free circulation of air under the frames, ſo neceſſary to the impregnation of the female flowers. The method is this:

They carefully gather the male flowers at a time when this farina is fully formed, and carry it to the female flowers, turning them down over them, and gently ſtriking, with the nail of one of their fingers, the outſide of the male flower, ſo as to cauſe the farina on the ſummits of the ſtamina to fall into the female flowers; by which means they will be ſufficiently impregnated. By practiſing this method, the gardeners have now a much greater degree of certainty than formerly, in procuring an early crop of cucumbers and melons; and by this method the floriſts alſo have arrived to greater certainty of procuring new varieties of flowers from ſeeds, which is done by mixing the farina of different flowers.

Sow Cucumber and Melon Seeds.

The beginning of this month, you ſhould remember to ſow ſome cucumber and melon ſeed, in order to raiſe plants for ridging out, under hand or bell glaſſes, in May.

Cabbages and Savoys.

If you did not tranſplant all the cabbage plants you intended to remove this ſpring, in March, let it be done at the beginning of this month, that the plants may take root before the dry weather comes on. Remember to water the plants as ſoon as they are ſet.

Let the earth be drawn up round the ſtems of forward cabbage plants; this will at once ſtrengthen them, and increaſe their growth.

Sow ſavoy and cabbage ſeed, to raiſe plants for a full winter crop. The ſituation of the ſpot where the ſeeds are ſown ſhould be open, and the ſeeds raked in equally.

You ſhould now prick out into beds thoſe cabbage and ſavoy plants which were ſown in February and March; for by this means they will gain ſtrength before they are planted where they are to remain.

The beds you intend for them, ſhould be prepared of good earth, in an open ſituation, and about three feet and a half broad. Let the largeſt plants be drawn out regularly from the ſeed-bed, and planted in the beds prepared for their reception, at four or five inches diſtance every way. Remember to water them immediately after they are planted, and to repeat it occaſionally in dry weather.

At the ſame time let the plants left in the ſeed-bed be cleared from weeds, and well watered to ſettle the earth about their roots, which had been diſturbed by drawing the larger.

Cauliflowers.

Draw up the earth about the ſtems of your early cauliflower-plants, for this will be of great ſervice in promoting their growth; but be careful that no earth be drawn into their hearts, as that will greatly injure them.

The cauliflower plants raiſed from ſeed ſown early in the ſpring ſhould, about the latter end of the month, be planted out for good, in an open ſituation, on a piece of rich ground, into which ſome good rotten dung has been dug. They ſhould be planted at about two feet and a half diſtance every way.

As ſoon as they are planted let them be watered, and the operation frequently repeated in dry weather, till the plants have taken root.

Let your bell-glaſſes be now raiſed on props, in order to give the plants more air; and whenever any gentle ſhowers fall, remember to take them entirely from the plants, for nothing refreſhes them more than gentle ſhowers.

As ſoon as you find your plants grow ſo faſt as to fill the glaſſes with their leaves, dig ſlightly about the plants, and raiſe the ground about them in a bed, large enough to ſupport the glaſſes, about four inches high, which will give your plants a great deal of room, by raiſing the glaſſes ſo much higher, when they are ſet over them again; and by this means you may keep them covered till the middle of this month, which could not otherwiſe be done without prejudice to the leaves.

Plant Kidney-Beans.

At the beginning of this month you may plant kidney-beans of the early kind, on a ſpot of dry ground, defended from cold winds, and open to the ſun.

Let

Let them be dropped three inches apart, into drills an inch deep, and two feet and a half aſunder. Let the earth be drawn equally over them, but do not let them be covered above an inch deep.

Remember to chuſe a dry ſeaſon for planting theſe beans, becauſe much wet will rot them; a rainy ſeaſon is therefore very improper for this work.

Kidney-beans for a principal crop may be planted about the middle of this month. The ſpeckled dwarf kidney bean, and the Batterſea white, are the proper kinds for planting now.

They ſhould be planted in an open ſituation, and the rows two feet and a half, or three feet diſtant from each other.

Mr. Miller recommends the ſcarlet bean, as preferable to all the other ſorts in goodneſs, and at the ſame time as much hardier. This ſort may now be ſown in the ſame manner, and on the ſame ſoil, as thoſe mentioned above; but they will be a fortnight later. This defect will, however, be well ſupplied by the continuance of the ſcarlet bean; for it will continue till the froſt puts a ſtop to it in autumn. At the ſame time the pods of this ſort, when old, are ſeldom ſtringy, have a much better flavour than the young pods of the other ſorts, and will boil greener.

Carrots and Parſneps.

You may yet ſow carrots; but it muſt be done at the beginning of the month, if you deſire to have your roots of a tolerable ſize.

But if a ſupply of ſmall young carrots ſhould be deſired, you muſt ſow a little ſeed at two different times this month; at the beginning and towards the latter end; by this means young carrots will be always ready for the table; for when the roots of the firſt ſowing become too large, thoſe of the ſecond will ſupply their place.

You may alſo, at the beginning of the month, ſow parſnep ſeed, where wanted; but if you delay it any longer, it will not ſucceed.

Spinnage.

Spinnage ſeed may be ſtill ſown; it will grow, if ſown any time this month; and where a conſtant ſupply of this plant is wanted, a little of the ſeed ſhould be ſown often, at leaſt once a fortnight.

Let the ſpinnage ſown the preceding months be now hoed, and the plants thinned out to four or five inches diſtant.

Raddiſhes.

You ſhould ſow a little raddiſh ſeed at three different times this month; for by that means a conſtant ſupply of young raddiſhes may be obtained. About eight or nine days between each ſowing will be ſufficient.

The ſeed ſhould be ſown in dry weather on a rich ſpot of ground, in an open ſituation; but you muſt remember to water it frequently, both before and after the plants are come up.

Indeed all the crops of raddiſhes ſhould be often watered in dry weather; for otherwiſe the roots will be ſmall, hot, and ſticky.

Let all your crops of raddiſhes be thinned, where they have come up too thick; the plants ſhould be at leaſt two or three inches aſunder; and the beds careſully weeded.

Aſparagus.

You may yet plant aſparagus if required; the plants will grow freely; but they rarely ſucceed well, if not planted by the middle of the month. The ſame method is to be obſerved in planting aſparagus now, as mentioned in the former month.

If any of your aſparagus beds remain undreſſed, let them be forked up by the end of the firſt week in this month, and raked immediately after; for the buds are now in great forwardneſs; ſo that great care is neceſſary not to injure them.

Artichokes.

Artichokes may be yet planted if required; they will ſucceed, provided you plant them early in the month.

The ſame method is to be obſerved in planting them, as deſcribed in the preceding month.

Beans.

Beans ſhould be planted at three different times this month, at the beginning, the middle, and the end.

The long podded beans are proper for planting now. This bean is a remarkable good bearer, and a fine eating bean; conſequently very proper for a family. This ſort may be planted any time this month. Allow a good diſtance between the rows.

You may alſo plant the Windſor, the Sandwich, or, indeed, any of the larger kinds.

The Mazagan and white-bloſſom bean, which are great favourites with many perſons, may alſo be planted any time this month. Let the rows be two feet and a half aſunder.

Both theſe are plentiful bearers, their ſtalks being generally loaded with pods from the very bottom to the top; and though ſmall, none exceed them for eating.

Peas.

A quantity of peas ſhould now be ſown to ſucceed thoſe ſown in March: and if a conſtant ſupply be deſired, ſome ſhould be ſown every fortnight at leaſt.

The marrowfats are very proper for ſowing at this ſeaſon of the year; though any other of the larger kinds of peas may be ſown any time this month; there is no danger of their ſucceeding if the weather be kind.

You may even ſow hotſpurs, or any of the ſmaller kinds of peas, at this ſeaſon; for theſe will ſucceed if ſown early.

Let the earth be drawn up to the ſtems of peas which are come up, and advanced a little height. This will greatly ſtrengthen the plants, and forward them in their growth.

When the plants are advanced about ſix inches in height, the ſticks ſhould be placed where you intend it; for the peas will now begin to want ſupport.

Potatoes.

If you omitted to plant potatoes in the former month, you may ſtill do it, but the ſooner it is done the better; for they rarely ſucceed well if planted after the middle of the month.

Turneps.

Turneps may be ſown any time this month; and the plants will appear in a few days after the ſeed is in the earth.

Let

Let the ſeed be ſown thin and equally in an open ſpot of ground, and raked in with a light and even hand.

Thoſe turneps which were ſown the former months ſhould now be hoed, and the plants thinned out to ſeven or eight inches diſtant from one another.

Lettuces.

Coſs, Sileſia, imperial, or any other ſorts of lettuce may be ſown any time this month; and as a regular ſucceſſion of theſe plants is generally deſired, a little ſeed ſhould be ſown about once a fortnight.

The ſpot of ground intended for this purpoſe ſhould be in an open ſituation, and the earth well broken. When the ground is prepared let the ſeed be ſown equally, not too thick, and raked in lightly.

The coſs, Sileſia, or any other ſorts of lettuce ſown laſt month, or in February, ſhould be now tranſplanted.

In order to this let a ſpot of ground be choſen, and a little rotten dung ſpread over it. Dig the ground well, bury the dung properly, and rake the ſurface very ſmooth.

The lettuces ſhould be planted about ten or twelve inches diſtant from one another, every way. When this is done let the plants be watered immediately, and the operation frequently repeated in dry weather, till they have taken root.

Small Salleting.

Creſſes, muſtard, rape, raddiſhes, and other plants of that kind, generally called ſmall ſalleting, ſhould be ſown once a week at leaſt.

In order to this a ſpot of rich ground ſhould be choſen, and the ſeeds ſown, each ſeparately, in ſhallow drills, and covered lightly with earth.

As ſoon as the ſeeds are ſown, water them moderately, if the weather be dry; for this will greatly promote their growth.

Celery.

Let a little celery ſeed be ſown the firſt or ſecond week in this month, in order to raiſe plants for ſucceeding thoſe which were ſown in March.

A rich light ſpot of earth muſt be choſen for this purpoſe, the ground broken fine, and the ſurface made very ſmooth and even. The ſeed is then to be ſown equally, not too thick, and either lightly raked in, or covered with fine earth about a quarter of an inch thick.

A few hoops ſhould, at the ſame time, be fixed acroſs the bed, and a mat drawn over the hoops occaſionally, when the ſun is hot, to prevent the earth from being too much dried. Water the bed now and then, and the plants, by this method, will riſe well, and grow freely.

Onions and Leeks.

You may yet ſow the ſeed of onions and leeks; either of them will ſucceed, if ſown at the beginning of the month; but if deferred any longer, there is great danger of ſucceſs, eſpecially with regard to the onions.

Purſlane.

Purſlane may now be ſown on a bed of light rich earth in the common ground. Water the bed often in dry weather, and ſhade it from the heat of the ſun, till the plants are come up, and have acquired a ſufficient degree of ſtrength.

Scorzonera and Salſafy.

About the middle of this month the ſeeds of ſcorzonera and ſalſafy ſhould be ſown for the principal crop; for that ſown any time before the middle of this month will ſoon run up to ſeed, and conſequently become uſeleſs.

Pot and Phyſical herbs.

Baum, penny-royal, and camomile, ſhould now be planted; but remember to plant them where they are to remain, and at about eight inches from one another.

Mint will alſo ſucceed if planted this month, eſpecially if the following method be purſued:

Draw up from the old beds a proper quantity of the beſt plants, that is, thoſe which are ſtrongeſt, and five or ſix inches high. Theſe plants muſt be taken up very carefully, with ſome roots to each.

Plant them in rows, allowing ſix inches between each row, and ſet them about ſix inches apart in each row. Water them as ſoon as they are planted, and repeat the operation frequently in dry weather, till the plants are well rooted.

Tanſey, tarragon, cives, and ſorrel, may alſo be planted at this ſeaſon; but remember to plant them where they are to remain, and to allow eight inches between every plant.

Slips of ſage may likewiſe now be planted; they will grow freely. Let the ſlips be about ſix or ſeven inches long, and planted in a ſhady border four or five inches apart from one another. Put the ſlips into the ground within two inches of their tops, and water them frequently in dry weather.

They will become fine plants by September, when they may be tranſplanted into beds of good light earth, at about eight or nine inches diſtance every way.

Thyme, hyſſop, ſavory, and marjoram will grow freely from ſlips or cuttings, planted any time this month. They ſhould be planted in a ſhady place, and treated in the ſame manner as before directed for ſage.

Rue, roſemary, lavender, ſouthernwood, wormwood, and lavender-cotton, may alſo now be propagated by ſlips or cuttings.

Theſe ſlips or cuttings ſhould be about ſix or eight inches long, and planted in a ſhady border ſix inches from one another. Remember to ſet the ſlips or cuttings full half way in the ground; and to water them frequently.

They may be tranſplanted, in September, to the place where they are intended to remain, at the diſtance of a foot from one another.

Naſturtium ſeed may be ſown in a drill about an inch deep. Let the ſeeds be placed two or three inches apart in the drill, and the earth drawn equally over them. They will grow and flouriſh freely.

Thyme, marjoram, ſavory, and hyſſop, may now be ſown ſeparate on a bed of light earth. Let the ſeeds be ſown, in ſeparate ſpots, on the ſurface, and raked in with a light and even hand.

Borage, bugloſs, clary, carduus, burnet, ſorrel, and marygold, may now be ſown in ſeparate ſpots of good earth, and raked in evenly.

It is not yet too late to ſow parſly, chervil, and coriander. Let the ſeeds be ſown equally, not too thick, in ſhallow drills, and covered with earth about a quarter of an inch thick.

The-

The Nursery.

Grafting.

The operation of grafting may ſtill be performed on fruit-trees of the lateſt kind; but it muſt be done during the firſt week in the month, or it will not ſucceed.

Hollies of the variegated kinds may be grafted till the middle of the month; for they are not ſo forward as fruit trees.

The common plain holly is the proper ſtock to graft the variegated kinds upon; but the ſtocks for this purpoſe muſt be four years growth at leaſt; if they are five or ſix it will be the better.

In order to this let ſome good cuttings, or grafts of the beſt variegated kinds be procured; they muſt be cuttings of the laſt ſummer's growth. Let theſe be carefully grafted, in the manner already deſcribed, and there will be little reaſon to fear the ſucceſs.

Inarching.

The operation of inarching may alſo be now performed on evergreens, or indeed, on whatever kind of trees or ſhrubs you may be deſirous of propagating by that method; which is principally intended for thoſe kinds of trees and ſhrubs which are not eaſily raiſed from ſeed, or any other general method; for it ſhould be remembered, that moſt ſorts may be propagated by inarching.

With regard to the evergreen kinds, they may be inarched with ſafety this month; but the other ſorts generally ſucceed beſt, when inarched at the beginning.

New Grafted Trees.

Your new grafted trees ſhould be carefully examined; for the clay is too often ſubject to fall off, or at leaſt crack in ſuch a manner as to admit both air and wet to the grafts.

Whenever you find this to be the caſe, let the old clay be taken entirely away, and ſome more, which has been previouſly well wet, and well wrought, placed immediately in its room. Obſerve to cloſe this perfectly in every part, ſo that neither air nor wet can penetrate to the graft.

If you find any ſhoots produced from the ſtock below the graft, let them be rubbed off cloſe; for theſe will impoveriſh the grafts, and perhaps in the end deſtroy them.

New Budded Trees.

Look over your new budded trees frequently about this time; for thoſe which were budded during the laſt ſummer will now be making their firſt ſhoots, and therefore require ſome care and attention.

Inſects often attack the tender ſhoots from the buds; and if not prevented will greatly hinder their progreſs, if not totally deſtroy them. Attention therefore is neceſſary; and by attention the injury may be, in a great meaſure at leaſt, prevented.

In order to this, examine the extremities of the young ſhoots, and where you find any of the leaves curled up, let them be carefully taken off, for they are full of ſmall inſects. By continuing this practice, the vermin will be deſtroyed, and conſequently the injury prevented from ſpreading any farther.

At the ſame time be very careful to rub off all the ſhoots beſides the bud, that the whole efforts of the ſtock may go to ſupport the buds; for all the others will have a tendency to injure and ſtarve them.

Tranſplanting.

At the beginning of this month, you may tranſplant moſt ſorts of ever-greens; particularly cedars, cypreſſes, firs, phillyreas, alaturnuſes and pyracanthas, bays, hollies, evergreen oaks, ciſtuſes, ciſtuſes, and ſeveral other ſorts of evergreens.

Remember to chuſe a calm cloudy day for this work, and if gentle ſhowers of rain fall, ſo much the better; for calm ſhowery weather is much the beſt for removing trees and ſhrubs at this ſeaſon.

As ſoon as they are planted, let them be well watered to ſettle the earth about their roots. Some mulch or litter ſhould alſo be laid on the ſurface of the ground; for this will prevent the ſun's drying the earth too much, and preſerve a proper degree of moiſture to the roots.

Deſtroy Weeds.

The weeds will now grow very faſt between the rows of young trees; let them therefore be deſtroyed, by hoeing the intervals.

But remember to uſe a ſharp hoe, and chuſe a dry day for this purpoſe. By this means you will eaſily keep your plantations clean and neat, without much labour; but if they are ſuffered to grow for any length of time, it will require double labour to extirpate them, beſides the injury they will do to the young trees.

Sow Ever-greens, Flowering-ſhrubs, &c.

All the ſeeds of ever-greens, and other ſeeds intended to be ſown this ſpring, muſt be put into the ground this month.

The ſeeds of hardy greens, ſuch as the cedar, cypreſs, juniper, ever-green oak, acorns, and bays, are the ſorts that will yet ſucceed.

They muſt be ſown in beds of light earth, in the common ground. Some indeed ſow them in boxes or pots, in order to remove them to different parts of the garden, according to the ſeaſon of the year.

Let the beds be about three feet broad, the earth broken very fine, and the ſurface laid perfectly even.

Each ſort of ſeed muſt be ſown ſeparate, and covered with a proper depth of rich light earth; that is, from half an inch to an inch, according to the ſize of the ſeed or kernels.

If you ſhould now ſow any of the more choice or tender kinds of trees or ſhrubs, you would do well to let it be done in pots, and the pots plunged into a hot-bed; for this will greatly forward their growth. Where this convenience, however, is wanting, they may be ſown in beds, in the common ground, where very few, eſpecially of the American ſorts, will miſcarry.

Management of Seed Beds.

Let the ſeed-beds be watered once every two or three days in dry weather, both before and after the plants begin to appear. Let the waterings be moderate and gentle; for if you at any time apply the water haſtily, it would probably waſh away the earth from the ſeed, and alſo from the young plants when they begin to appear.

You

You ſhould alſo be careful to ſhade, in the middle of hot ſunny days, all kinds of ſeedling trees and ſhrubs, from the time they appear till they have been up for ſome time. This will be almoſt as neceſſary as water.

It may eaſily be done by fixing hoops acroſs the bed, and drawing mats over them when neceſſary.

If your ſeeds are ſown in boxes, pots, or tubs, let them be removed to a ſhady ſituation about the middle or latter end of the month.

But wherever they are ſown, remember to keep the beds, pots, &c. free from weeds; for if this be neglected the weeds would choke the plants, as they grow much faſter. As ſoon therefore as any weeds appear, let them be taken away; at leaſt before they get any great head. This muſt be done carefully by hand weeding.

The FRUIT-GARDEN.

Plant Fruit-trees.

You may yet plant apple, pear, plum, and cherry trees, where wanting; they will ſtill ſucceed; but the ſooner it is done the better. It ſhould not be delayed beyond the firſt week in the month.

Be ſure you give each tree a good watering as ſoon as planted; it will be of the utmoſt ſervice, as it will nouriſh the tree, and ſettle the earth cloſe about its roots. The waterings ſhould be repeated once a week, in dry weather.

New Planted Trees.

All new planted trees in general ſhould be watered once a week in dry weather, and remember to water their heads as well as their roots.

At the ſame time let ſome mulch be laid on the ſurface of the ground round their ſtems; this, with moderate waterings, will preſerve a proper degree of moiſture to their roots, and prove very ſerviceable to their growth.

Vines.

As your vines planted againſt walls will, by the latter end of the month, have made ſome ſhoots, they ſhould then be looked over; and all ſuch as appear to be uſeleſs, rubbed off. The old branches generally ſend forth ſhoots; but as theſe rarely produce either grapes or wood proper to bear fruit, they ſhould all be rubbed off cloſe.

The ſhoots that ariſe from the laſt year's wood ſhould not be taken away at preſent, except where two ſhoots ariſe from one eye, the worſt of which ſhould be rubbed off; for if both are left they will ſtarve each other, ſo that the fruit of neither will be good.

Having thus cleared away the uſeleſs ſhoots, let the others, when of a due length, be trained cloſe to the wall in a regular manner, ſo that each may equally enjoy the advantage of the ſun and air; this will at once promote the growth of the ſhoot and that of the fruit.

By practiſing this method the grapes will be fine, the bunches large, and they will ripen early and well.

With regard to vines planted in the vineyard, ſtakes ſhould now be fixed near them for their ſupport, provided it was not done before. Let theſe ſtakes be firmly fixed in the ground, and the vines tied to them at equal diſtances.

Remember to keep the ground between the rows of vines entirely free from weeds; for the ſucceſs, with regard to the growth and fineneſs of the fruit, greatly depends upon keeping the ſurface clean.

Whenever, therefore, any weeds make their appearance, let them be deſtroyed by the hoe the firſt dry day, before they arrive at any conſiderable bigneſs.

Peach, Apricot, and Nectarine Trees.

About the latter end of this month, look over your peach, apricot, and nectarine trees, diſplacing all ſuch young ſhoots as are evidently uſeleſs. That is, all ſhoots produced foreright ſhould be rubbed off cloſe: together with thoſe which ariſe in parts of the tree where they are not wanted, or where they cannot be neatly trained in.

But all ſhoots properly ſituated for training in muſt be left, and, when of a proper length, trained cloſe and in a regular manner to the wall.

Pruning.

If any pruning ſtill remains to be done, let it be entirely finiſhed the firſt week in the month; for after that time no tree ſhould be touched with the knife.

Grafting.

Apples, pears, plums, and cherries, may yet be grafted with ſucceſs, provided the operation be performed at the beginning of the month; but after that time the grafts will not take.

New Grafted Trees.

Look frequently over your new grafted trees, to ſee if the clay keeps cloſe about them; for it is apt to crack and fall off. Where this happens, let the old clay be taken away, and new placed in its ſtead; for no wet muſt be admitted to the graft.

At the ſame time all the ſhoots that riſe from the ſtock below the graft, muſt be rubbed off as ſoon as produced; for theſe, if ſuffered to remain, would rob the graft of its nouriſhment, and, conſequently, prevent its ſhooting.

New Budded Trees.

Your new budded trees muſt alſo now be looked over; we mean thoſe which were budded laſt ſummer; for they will now begin to ſhoot. Examine them carefully with regard to inſects, deſtroying them wherever they are found. If the leaves curl up, inſects are the cauſe of it, and will, if not prevented, ſpoil the ſhoot. Let therefore the curling leaves be picked off; this will prevent the miſchief from ſpreading further.

Remember that no ſhoots which come from the ſtock ſhould be ſuffered to remain. Let them, therefore, be taken off as ſoon as they appear, and nothing be left to draw nouriſhment from the bud.

Thinning of Fruit.

About the latter end of this month, look over your apricot trees, and where you find the fruit too thick, let ſome of it be taken away; obſerving to leave the moſt promiſing and beſt ſhaped fruit, but not ſo cloſe together as to touch when grown to their full ſize.

In order to this begin at one ſide of the tree, and look over the branches regularly, one by one, ſingling out on each branch all the fruit you would leave, before any are taken away. When the faireſt and beſt ſituated fruit are thus ſingled out, let the reſt on that branch be cleared away. When you have finiſhed one branch go to the next; and proceed regularly from branch to branch through the whole tree.

Strawberry Beds.

Take care that your ſtrawberry beds be now kept free from weeds. You ſhould alſo clear away the runners from the plants as they advance; unleſs new plantations are wanted, when ſome of the ſtrongeſt runners ſhould be ſuffered to remain.

They will require very frequent waterings in dry weather; eſpecially when they are in bloom; for if they are not well ſupplied with water at that ſeaſon, the crop will be thin, and the fruit ſmall and ill taſted.

Deſtroy Inſects.

Inſects are very deſtructive to fruit-trees, ſo that too much care cannot be taken to deſtroy them. This is the ſeaſon when they begin to breed on the leaves of young trees, and alſo on thoſe of old trees, which are of weaker growth. Proper means ſhould therefore be taken to remove the evil before it ſpreads too far.

In order to this look over your trees frequently; and where you preceive any of the leaves curled up, you may be ſure to find inſects there. Let the worſt of theſe leaves be taken off immediately, and the branches well and frequently watered in dry weather.

If you perceive your trees, whether old or young, over-run with inſects, pluck off all the curled leaves, and ſcatter tobacco duſt over the branches where the inſects are found. This ſhould be done in the morning, and ſuffered to remain two or three days on the tree.

If tobacco duſt cannot eaſily be had, ſteep ſome tobacco in water, about twenty-four hours, and ſprinkle the trees where the inſects are, with the ſolution, which will totally deſtroy them, without injuring either the fruit or the tree.

The PLEASURE or FLOWER-GARDEN.

Sow Perennial and Biennial Flowers.

You muſt now ſow all the perennial and biennial plants intended to be ſown this ſeaſon.

The ſorts proper to ſow now are ſweet-williams, wall-flowers, columbines, ſtock july-flowers, Canterbury bells, pyramidal campanulas, tree primroſe, Greek valerian, hollyhocks, French honeyſuckles, ſingle catchfly, roſe campion, and ſcarlet lychnis.

The ſeed ſhould be ſown in beds of light earth three feet wide; and the larger ſort of ſeed covered about half an inch, and the ſmaller about a quarter of an inch deep.

Sprinkle the beds frequently with water, in dry weather, both before and after the plants appear above the ſurface. By this means the plants will grow freely, and ſoon acquire a ſufficient degree of ſtrength.

Tranſplant Perennial Plants.

You may yet tranſplant perennial plants with ſucceſs, provided it be done at the beginning of the month. Moſt of the ſorts will ſucceed at this ſeaſon, particularly golden rods, Michaelmas daiſies, perennial aſters, perennial ſun-flowers, Canterbury bells, columbines, Greek valerian, ſcabiouſes, campanulas, catchfly, roſe campion, rockets, lychniſes, batchelors buttons, ſweet williams, pinks, carnations, polyanthuſes, primroſes, double daiſies, double cammomile, thrift, London pride, gentianellas, and ſome others.

Remember to take up the plants with balls of earth about their roots, if poſſible, and plant them again immediately in the places where they are to remain.

Water them well as ſoon as planted, and repeat the operation frequently in dry weather. By this means the plants will all flower this year, each at its reſpective ſeaſon.

Dreſs the Pots containing Perennial Plants.

Thoſe pots of perennial plants which were not dreſſed in March, muſt now be done in the following manner.

Looſen the earth on the top, and round the ſides of the pot; take out the looſe earth, and clear away all the decayed leaves from the plant: when this is done, fill the pots again with rich new earth, and give the plants a gentle watering.

This dreſſing will be very beneficial to the plants, and ſhould be done the beginning of this month, if omitted in March.

Remember alſo to water all the plants that are in pots, in dry weather. This ſhould be done frequently, or the plants will miſcarry.

Tender Annual Plants.

A new hot-bed ſhould now be made for the reception of the tender annuals ſown in February.

By tender annuals, we mean cockſcombs, tricolars, double balſams, globe amaranthus, the egg plant, the double ſtamonium, and the ficoides, or ice plant.

Where theſe curious plants are deſired to blow in any tolerable degree of perfection, they muſt now be brought forward by the aſſiſtance of a regular and proper degree of artificial heat; and if that circumſtance be duly attended to, there is no danger of the plants proving ſtrong, and their flowers being large and beautiful.

The bed for this purpoſe ſhould be full two feet thick, and made of the beſt hot dung, well prepared.

Set the frame upon the bed; and when the burning heat is over, lay on the earth, which muſt be light and dry, not ſifted, but very well broken with the ſpade and hands, and laid ſix or ſeven inches thick on every part of the bed.

In about twenty-four hours after the earth has been laid on the bed, it will be in a proper condition to receive the plants, which muſt then be taken out of their old bed, with a ball of earth about their roots, and planted in the new bed full ſix inches apart, every way. Give them a little water as ſoon as they are planted, to ſettle the earth about their roots; put on the glaſſes, and when the ſun is ſo powerful as to cauſe the plants to flag, throw a ſingle mat over the glaſſes, continuing this practice till they have taken root.

Remember to raiſe the glaſſes a little every day, that the ſteam from the dung may paſs off freely; and if you perceive any quantity of ſteam in the bed, let one corner of the glaſſes be raiſed at night, hanging a mat before the opening.

As

As ſoon as you perceive the plants have taken root, and begin to puſh, let them have plenty of free air every day, in mild and calm weather; for nothing ſtrengthens plants more than a free circulation of air. But the glaſſes muſt be ſhut down every night, provided there be no ſteam in the bed, and a mat thrown over the glaſſes.

Remember alſo to refreſh them frequently with water, giving them a little at a time; for this will greatly improve their growth.

You muſt be careful to obſerve, that when the plants are grown ſo high as almoſt to touch the glaſſes, the frame muſt be raiſed about ſix inches, at the bottom, in order to give them room to ſhoot; continuing to raiſe the frame in proportion to the growth of the plants.

But you muſt remember to cloſe up the vacant ſpace at the bottom every time you raiſe the frame, by nailing mats at the bottom, that no air may enter but at the proper place. Multiplying or drawing frames are very uſeful for this purpoſe, as they may be raiſed to the height deſired, without any trouble or danger of injuring the plants, by an admiſſion of too much air at the bottom. A drawing frame may be made in the following manner.

Let two, three, or more different frames be made of the ſame length and breadth, each about nine or ten inches deep, except the frame for the glaſſes, which muſt be twelve inches deep in front, and eighteen at the back. Let all theſe be made to fit one another in a very exact manner, ſo as to be eaſily fixed upon the top of one another, and, when fixed in that manner together, to appear as one frame.

The very nature of the conſtruction will ſufficiently ſhew the manner in which they are to be uſed; it is this:

Let the frame containing the glaſſes be firſt placed upon the bed; when the plants have almoſt reached the glaſſes, let the frame be taken up, and one of the ſhallow frames placed in its ſtead, fixing the frame with the lights upon it.

By the addition of this frame, there will be ten inches more room for the plants to ſhoot; and when they have filled that ſpace, let another frame be added, obſerving always to place the frame containing the lights uppermoſt.

About the middle of this month, another hot-bed muſt be prepared for thoſe cockſcombs, tricolars, and other plants of that kind, ſown in March.

This bed muſt be at leaſt twenty inches thick of dung, a frame fixed on it, and, when the burning heat is over, covered with dry earth five or ſix inches deep.

The plants are to be pricked into this bed at the diſtance of three or four inches from one another. When this is done, give the plants a gentle watering; put on the glaſſes, and ſhade them from the ſun, till they are well rooted.

Remember to raiſe the glaſſes every day as occaſion requires, to let out the ſteam, and give the plants freſh air.

The ſame management, in every reſpect, muſt be purſued for theſe, as for thoſe ſown in February, and which has been already laid down.

Hardier Kinds of Annual Plants.

Some of the more hardy kinds of annual plants will now be fit to be removed; particularly the marvel of Peru, China aſters, balſams of the common kinds, African marygolds, chryſanthemums, ſcabiouſes, capſicums, and ſeveral others.

A ſlight hot-bed muſt therefore be made for theſe plants about the middle of this month; twenty inches of dung will be full ſufficient, covered with five or ſix inches of good earth.

When the bed is in a proper condition, draw from the ſeed-bed ſome of the ſtrongeſt plants, and prick them into the new bed four or five inches diſtant from one another, giving them a little water. Place the frame on the bed, or, if a frame be wanting, fix ſome hoops acroſs the bed, and let mats be drawn over them every night, and alſo during the day, when the weather is cold. At the ſame time remember, when the weather is warm, to ſhade the plants from the rays of the ſun, till they have taken root.

In this bed the plants are to remain about five weeks, when they may be taken up, with a ball of earth about their roots, and planted where they are intended to flower.

Sow Chryſanthemums, Marvel of Peru, &c.

The ſeeds of chryſanthemums, marvel of Peru, African marygolds, balſams, China after, Indian pink, and ten-week ſtock, may yet be ſown with ſucceſs.

But it muſt be done the firſt or ſecond week in the month, on a moderate hot-bed, often refreſhed with water.

The bed muſt be covered with a frame, or arched over with hoops, and mats drawn over it every night in bad weather.

As ſoon as the plants appear, let them have plenty of freſh air, by removing the coverings entirely every mild day; remembering to cover them at night, eſpecially in bad weather.

Theſe plants will be fit to prick out into beds of light earth, in the natural grounds, about the middle of May, where they are to continue a month, or five weeks, and then taken up with balls of earth about their roots, and planted in the borders, where they are to flower.

Sow Hardy Annuals.

It is not yet too late to ſow the ſeeds of hardy annuals in the borders, and other parts of the garden.

The following ſorts will yet ſucceed, namely, convolvulus major and minor, Tangier and ſweet-ſcented peas, naſturtiums, lupins, larkſpur, flos Adonis, ſweet ſultan, candy tuft, dwarf lychnis, lobels, catchfly, Venus navelwort and looking-glaſs, Virginia ſtock, ſnails, caterpillars, lotuſes, dwarf and large annual ſun flower, laveteras, oriental mallows, and many other kinds of hardy annuals.

The ſeeds ſhould be ſown ſeparate, in ſmall patches, in different parts of the borders, according to the method deſcribed in the two former months.

Remember to water the patches frequently in dry weather, both before and after the plants appear; for otherwiſe they will be weak, and their flowers indifferent.

After the plants have been up about a fortnight, let them be thinned, where they appear too thick, remembering to clear away the weakeſt, and leaving the ſtrongeſt plants to flower.

Management of Tulips, Hyacinths, Ranunculuses, &c.

Tulips, hyacinths, ranunculuses, and anemonies, will now advance apace towards their bloom.

The more curious sorts of these flowers must therefore be now managed with care. They must be defended from heavy rains, and high winds; nor must the sun be suffered to shine freely upon them; the former would greatly injure the plant, and the latter cause them soon to decay.

Hoops must therefore be kept constantly over the beds, and mats, or canvas, drawn over them occasionally. By this means you will not only preserve the beauty of the flowers, but also continue the bloom much longer.

Remember that the hoops must be pretty lofty, and nailed to stakes about three feet high, fixed at proper distances on each side of the bed.

Let the mats, or canvas, be drawn over the hoops, about nine or ten in the morning, every sunny day, and continue there till four or five in the afternoon, while the plants are in flower.

When it rains hard, or when the winds are strong, the mats must also be drawn over the hoops; otherwise the flowers will be beat down, and many of their stalks broken.

The flowers should also be sheltered every night, when there is the least appearance of bad weather.

Some of the stalks, particularly of the hyacinths, are not able to support their flowers; in this case, short sticks should be placed near each plant, and the stalk neatly fastened to it with yarn, bass, or some other soft substance.

Carnations.

You must now support the flower-stalks of your carnations, as they will shoot apace at this season.

In order to this, let a sufficient number of handsome straight sticks, of a proper length, be procured. These sticks must be thrust down carefully, near the plants; and the flower stems, when advanced to a proper height, fastened to them. Remember to tie them between the joints, that the stalks may have full liberty to shoot; and as the stalks advance higher, continue to tie them carefully to the sticks.

It will also be necessary to place sticks near such carnations as are planted in the borders, for such supports will soon be necessary.

But a further care is necessary for those carnations that are planted in pots; indeed too much attention cannot be paid them at this season. Every thing that has a tendency to encourage their growth should now be put in practice.

The pots should be kept perfectly free from weeds, and the plants from decayed leaves. The surface of the earth in the pots should be stirred now and then; for this will at once give an air of neatness to the whole, and greatly encourage the plants in their growth.

Let the plants be often watered in dry weather; every second or third day, at least; but let it be moderate. For if this necessary assistance be wanting, the flowers of the plants will be at once small, and ill-shaped.

Sow the Seeds of Carnations and Pinks.

It is not yet too late to sow the seeds of carnations and pinks; especially if it be done the first or second week in the month.

In order to this, let a small spot of rich light ground be neatly dug, and the surface laid very even. Divide this spot into beds of about three feet broad, and sow the seed of each sort separately, on the surface, pretty thick; covering the seed with fine light earth, about a quarter of an inch deep.

If the weather should prove dry, these beds should be often sprinkled gently with water; and the plants will appear in about forty days after they are sown.

This is not the place to give the further management of these plants; but it will be resumed in the succeeding months.

Management of Auriculas.

Care must now be taken to protect the more curious sorts of auriculas from heavy rains, strong winds, and too much sun; for they will now begin to blow.

Were the sun admitted to shine freely on the plants, they would soon fade; a small shower of rain, or a blast of wind, would deprive these flowers of the mealy dust which covers their surfaces, and composes a principal part of their beauty.

Let therefore the pots, as fast as the flowers open, be removed, and placed on the shelves of the stage, or where the flowers may be occasionally protected from such weather as would effectually deface the bloom.

Remember that the top of the stage must be always covered, but the front only occasionally. In order to this, a mat or canvas should be nailed to the front, by way of a curtain, and contrived in such a manner, that it may be let down or drawn up at pleasure. By this means the flowers may be effectually sheltered from sharp, or strong winds, and driving rain. But remember to let the curtain be let down no lower than will be sufficient to shade the plants; and never to let it remain down any longer than is absolutely necessary for the defence of the flowers.

Examine the pots once every day, at least, after they are placed on the stand, to see where water is wanting, and to let that want be immediately supplied. But remember not to let the water fall on the flowers, for that would wash off their beautiful dust; and that it be always given them in moderate quantities.

Let the surface of the earth in the pots be kept perfectly neat, free from weeds, and every sort of litter; nor ever suffer any decayed leaves to remain on the plants: let them be taken away as soon as discovered.

If you intend to save any seed from your auriculas, remember to mark the plants you destine for this purpose when in full bloom. A large flower that blows regularly, and lays itself perfectly flat, should be chosen for this purpose. The colours should be lively; the eye large and bright; and the stalk tall, straight, and proportionally strong.

As soon as you have marked the flowers you intend for seed, let the pots be immediately removed off the stage, and plunged into a border where the plants can enjoy the benefit of the morning sun till about ten or eleven o'clock, but no longer.

Remem-

Remember to water them frequently in dry weather; to ſuffer no weeds to grow either in or near the pots; nor let them at any time be too much ſhaded with any large growing plants.

But auriculas are not only increaſed from ſeed, they are alſo propagated from ſlips, or ſuckers, taken from the old plants; and this is the ſeaſon to take them off, and plant them.

Each ſlip ſhould be planted ſingly, in a ſmall pot of freſh earth, and have a little water given them as ſoon as they are planted. The plants will take root freely, provided they are watered moderately now and then, and depoſited in a ſhady place.

Management of Seedling Auriculas and Polyanthuſes.

Theſe plants, when young, are not able to bear the ſun; conſequently they muſt be occaſionally ſhaded from it.

Let therefore the tubs, pots, or boxes, in which theſe plants are growing, be, about the latter end of the month, removed into the ſhade. But remember to chuſe ſuch a ſituation as is open to the morning ſun till about nine o'clock, and ſhaded the remainder of the day.—They muſt be often refreſhed with water, in dry weather.

You may yet ſow the ſeed of polyanthuſes and auriculas, provided it be done the firſt week in the month; but, after that time, there is great danger of its not ſucceeding.

Plant flowering Shrubs.

The althæa frutex, Perſian lilac, bladder and ſcorpion ſenas, honey-ſuckles, jaſmines, ſyringas, laburnums, and ſome other flowering ſhrubs, will yet bear tranſplanting; but the ſooner it is done, the better; it ſhould not exceed the firſt week in the month.

Remember to water them well, when they are firſt planted; and, if the ſeaſon be dry, repeat the operation once or twice a week.

Plant Evergreens.

Several evergreen trees and ſhrubs, particularly pines, firs, cypreſs, junipers, and cedars; hollies, bays, yews, laurel, Portugal laurel, lauriſtines, phillyreas, alaturnuſes, pyracanthas, citiſuſes, ciſtuſes, arbutus, ever-green caſrine, and mangolias, may ſtill be planted; but it ſhould be done the firſt week in the month.

Remember to open a large hole for each tree or ſhrub, and, when deep enough, to looſen the ground well at the bottom. When this is done, pour into each of them a pot of water, and work up the earth and water with your ſpade. Then place each plant upright in its hole, and let the earth be well broken and filled in about the roots. When all is in, tread the earth gently round the ſtem, and form the upper part into a hollow form, to contain a proper quantity of water.

When you have not far to bring the plants, let them be taken up with balls of earth about their roots, and placed in the holes with the balls entire.

But, however that be, remember to give them a good watering as ſoon as planted, in order to ſettle the earth about their roots; and then to lay ſome mulch or litter on the ſurface of the ground round the ſtem of each plant; for, otherwiſe, the earth will dry too faſt about their roots, and conſequently prevent their growth, if not totally deſtroy them.

You muſt alſo remember to place ſtakes near ſuch as require ſupport; and to faſten the ſtem of the plants to them, that the wind, by blowing them to and fro, may not diſplace their roots.

Plant Box and Thrift.

Box and thrift may be tranſplanted for edgings to beds, or borders, where wanted; both will grow freely; and the latter, if planted cloſe and neat, will form a very agreeable edging.

Stick and trim flowering Plants.

You muſt now carefully inſpect your flowering plants, and place ſticks to ſuch as ſtand in need of ſupport, before they acquire an unſightly growth.

Let the ſticks be proportioned to the height of the plant, fixed firm and upright in the ground, and the ſtalks or ſtems of the plants tied neatly to them with ſome ſoft ſubſtance.

Clear away all the decayed leaves from every part of the plant, together with all the ſtraggling and broken ſhoots; for theſe will injure the plant, render it unſightly, and prevent its growth.

Break up and turn Gravel Walks.

Such gravel walks as were not broken up and turned in March, muſt now be put in order for the ſummer ſeaſon. By turning them at this time of year, you will at once deſtroy the weeds and moſs, and give the ſurface a freſh and lively appearance, which will continue the whole ſummer.

The method laid down in the foregoing month muſt be obſerved in turning, or laying, gravel-walks at this ſeaſon. That is, it muſt be done in dry weather, and when you have advanced about twenty feet, to tread, rake, and roll the ſame regularly as you go on; for gravel never binds ſo well as when it is firſt ſtirred. The roller alſo will, at that time, have a much greater effect in making the body of the walk firm, and the ſurface cloſe and even.

It will be alſo neceſſary to roll gravel walks that have been either new made, or turned, very frequently, twice a week, at leaſt; for by frequent rolling, the walks will be rendered firm and beautiful, and the growth of moſs and weeds in a great meaſure prevented.

Mow and roll Graſs Walks, &c.

This is the ſeaſon for putting graſs walks, lawns, and other pieces of graſs in the garden, into the beſt order. Let the graſs therefore be regularly mown, and frequently rolled. In mowing your graſs, be particularly careful to cut it as cloſe and even as poſſible; for the walks and lawns will have a very diſagreeable appearance, if the ſtrokes of the ſcythe are ſeen.

It will be neceſſary to mow your graſs-walks once a week, to keep them in any tolerable order; for if you ſuffer the graſs to grow rank, you will find it, at once, laborious and difficult to mow it ſmooth and level; but if the ſcythe be frequently applied, the mowing will be performed with eaſe and exactneſs. Remember to roll the graſs the day before you intend to cut it; for you will find the benefit of it in the morning.

Let your graſs-walks be rolled frequently; for this will give the walk a very neat appearance, render the

graſs

grass thick at the bottom, and greatly contribute to the ease of the mower.

Whenever you perceive any worm-casts upon your grass, let these be broken, and spread with a pliable pole, before you apply the roller; for the worm-casts, when first broken and spread, will readily stick to the roller, especially if the roller be of wood. By this means the grass will be made perfectly clean, and you may mow it to a much greater degree of exactness.

Destroy Weeds.

Weeds will now rise plentifully, in every part of the garden, among the plants; let them therefore be destroyed, either with the hoe or hand, before they grow larger.

Remember to keep your hoe sharp, and to take the advantage of a dry day to use it, cutting the weeds up clean below the surface. At the same time, let the ground, in the intervals between the plants, be stirred as you go on, and all the dead leaves and straggling shoots be taken away.

Rake the borders neatly with a small rake, taking away all the weeds and litter, and laying the surface very smooth and even.

MAY.

Work to be done in the KITCHEN-GARDEN in May.

Cucumber Plants in Frames.

YOUR cucumber plants under frames will now require an assiduous attendance, as they will be in full perfection for bearing.

They must be frequently, twice a week at least, refreshed with moderate waterings; for if this be omitted, many of the fruit will drop off, and the remainder prove small and ill-tasted. The best time for doing this, is about three or four o'clock in the afternoon.

Air must be freely admitted to the plants every warm day; for the sun has now great power; so that, if the glasses were kept too close, the heat would destroy the plants. Let therefore the upper ends of the lights be raised every warm sunny morning, about seven or eight o'clock; and continuing to raise the glasses higher, in proportion as the heat of the day increases.

But remember to shut the lights down every warm evening about six or seven o'clock; in cold evenings, shut them down an hour or two sooner.

Let the plants be shaded from the sun in very hot days, from eleven till two o'clock.

Remember to keep your glasses at a considerable distance above the plants. This distance should not be less than eight inches in front, and twelve at the back of the frame. This will give them a larger space of air, and, at the same time, lessen the fierce effects of the sun; so that there will be less danger of scorching their leaves, and parching up their roots.

Let therefore the frame be now raised to the above height, and you will soon perceive the benefit of it, by the growth of the plants.

Cucumbers under Hand or Bell Glasses.

You may now plant out cucumbers under hand or bell-glasses; and those planted at the beginning of the month, will have fruit fit for the table about the beginning of June, and continue bearing till the plants are destroyed by the cold weather.

But a slight hot-bed must be made to plant them in, in order to bring them forward, at first; and it will be the best method to have all, or, at least, the greater part of these hot-beds within the ground.

Let a rich spot of ground be chosen for this purpose, and there dig a trench two feet six inches wide, and about twelve or fifteen inches deep, laying the earth thrown out along the sides of the trench.

Fill this trench with fresh horse-dung, and raise it about three inches above the surface of the ground; for the bed must be, at least, fifteen or eighteen inches thick of dung.

When this is done, cover the bed with the earth that was thrown out of the trench; this must be laid eight or nine inches thick over the top of the dung, and the earth extended six inches on each side of the bed beyond the dung.

Then mark out the holes for the plants exactly in the middle of the bed, at three feet six inches from one another.

In each of these holes set two or three good plants, and give them a little water. Put on the glasses, and shade the plants from the sun till they have taken root.

The long prickly, and the long green and white Turkey cucumbers are the most proper for these plantations.

Remember to give these plants air every day in calm warm weather, by tilting up one side of the glasses, and also to refresh them now and then with moderate waterings.

But where proper plants cannot be readily procured to plant in the above bed, let some good seeds be put in; the plants will soon come up, and produce fruit at a very acceptable season.

In order to this, when the bed is made as above directed, mark out the holes for the seed about three feet and a half asunder; make the holes in the form of a shallow bason, about an inch and a half deep; and each of them about ten inches over.

In each of these holes put eight or nine good plump seeds, cover them about half an inch deep with earth, and put the hand or bell-glasses over them.

When the plants have been up about ten or twelve days, they must be thinned, leaving only four of the strongest plants in each hole; drawing, at the same time, some earth about their shanks.

These seeds, if sown the first or second week in May, and properly managed after they come up, will produce fruit fit for the table by the latter end of June.

Sow

Sow Cucumbers for Pickling.

The ſeeds intended to raiſe cucumbers for pickling ſhould be ſown in the natural ground, about the middle of the month; unleſs the ſeaſon be cold, or very wet, when it will be better to defer it till the laſt week in May, or the beginning of June.

Let a piece of rich open ground be prepared for theſe ſeeds, divided into beds three feet broad, and alleys of twelve inches broad between the beds. You may, if ground be wanting, plant rows of lettuces, ſavoys, or dwarf kidney-beans, between the beds.

When the beds are thus laid out, place marks for the holes exactly in the middle of the beds, three feet and a half aſunder. Dig the places where the holes are to be made, and break the earth well with the ſpade. This being done, form the holes, with the hand, like a ſhallow baſon, about an inch and a half deep, and ten inches over; ſowing in each hole eight or ten ſeeds, and covering them about half an inch deep with earth.

If the weather ſhould prove hot immediately after the ſeed is ſown, it will be neceſſary to ſprinkle the holes with a little water; but be ſure to let the ſprinkling be very moderate, for too much moiſture would rot the ſeed.

Remember to thin the plants when they have been up about a fortnight, leaving only five or ſix of the beſt and ſtrongeſt plants in each hole.

It is the common practice with gardeners, where room is wanted, to ſow the ſeed intended to raiſe cucumbers for pickling, between the rows of early cauliflowers, and other vegetables of that kind, allowing the ſame diſtance between the holes as above mentioned; and as the cauliflowers will be gone by the time the cucumber plants begin to puſh out their runners, they will not be injured by them.

In cold wet ſeaſons, many of the gardeners near London ſow theſe ſeeds on a ſlight hot-bed, and remove the plants when they have been up about a week or ten days. Their method is this:

They make a bed with new horſe-dung about a foot thick, adapting the breadth and length to the quantity of plants they intend to raiſe. This bed they cover with earth about three inches deep, drawing drills with their fingers acroſs the bed. In theſe drills the ſeed is ſown thick, and in cluſters, each conſiſting of eight or ten good ſeeds; and covered with earth about half an inch deep. The ſeeds in the cluſters almoſt touch one another, but a clear ſpace of about three inches is allowed between them: the drills are about two inches aſunder. The ſeed being thus ſown in patches, it will riſe in the ſame manner; and when the plants are fit to be removed, they are taken up in cluſters as they grow, with the earth, which will readily hang about their roots, and planted in the places where they are to produce their fruit; allotting one bunch of plants to a hole, and giving them immediately a little water. They will readily take root without flagging their leaves, and require no farther care, except a little water occaſionally in dry weather.

This is a very good method in bad ſeaſons, as a very large number of plants may be raiſed by it, with very little trouble.

Melons in Frames.

Your melon plants, whether under frames or bell glaſſes, ſtill require particular attention.

Some of the moſt early plants in the frames will ſhew fruit in plenty, many of which will be ſet, and others ſwelling. All the aſſiſtance, therefore, in the power of art ſhould be given the plants, in order to procure a full crop of fruit.

A proper degree of heat in the beds, while the fruit is ſetting, and ſome time after, is a principal thing to be remembered; for a kindly warmth is as neceſſary to ſwell the fruit after they are ſet, as it was to encourage the plants to produce them at firſt.

In order therefore to keep up this kindly warmth, your beds ſhould be often examined; and whenever you perceive the heat to have declined conſiderably, let a freſh lining of well prepared hot dung be immediately applied to one or both ſides of the beds, as you ſee occaſion: for though there are often very warm days in this month, yet there are often cold nights; and, conſequently, it will be neceſſary to preſerve a due degree of heat in the beds, as many of the melons will otherwiſe turn yellow and fall off, and the reſt neither ſet nor ſwell kindly.

At the ſame time the plants in frames muſt be allowed a good quantity of freſh air every day when the weather is calm and mild. In order to this, the upper end of the lights muſt be raiſed with props, two, three, or four fingers breadth high, in proportion to the warmth of the day; and ſhut down cloſe every evening about four or five o'clock. By this means the plants will be ſtrengthened, and the ſetting and free ſwelling of the fruit greatly promoted.

Remember alſo to cover the glaſſes every night with mats, during this month. When the air is cold, the mats ſhould be thrown over the glaſſes about five in the evening; but when warm, it will be ſoon enough to do this at ſix or ſeven.

When the morning is warm and ſunny, let the mats be removed by ſix; but if the weather be cloudy, ſeven will be ſoon enough.

You muſt likewiſe remember to water your melon plants in frames, for they will require a little now and then, when the weather is warm and ſunny. But let theſe waterings be always moderate, and not too often, for too much water would chill the young fruit, and prevent their ſettling. Once in ten days will therefore be often enough, and two pots of water ſufficient for a three-light frame.

Let always a moderate warm day be choſen for watering your plants, and let it be done about three or four o'clock in the afternoon. Remember to ſhut down the lights immediately after watering, and, if the ſun ſhines, throw a mat over the glaſſes, and let it continue there an hour or two.

In watering theſe plants, let as little as poſſible touch the fruit that are about ſetting, or newly ſet. The greater part of the water ſhould be applied towards the extreme parts of the bed; and a little only near the head, or main ſtem of the plant.

When the weather is very warm, you will find it of great advantage to ſhade the plants from the ſun, during two or three hours in the hotteſt part of the day. Thin mats ſhould be thrown over the glaſſes about eleven o'clock, and removed about two.

As the melons ſet, remember to place a piece of tile under each, to preſerve them from the damp of the earth in the bed.

It:

It will alſo be neceſſary to raiſe the frame, whenever you perceive the plants too near the glaſſes. This is done by placing bricks, or ſquare pieces of wood under each corner of the frame: about ſix inches riſe will be ſufficient.

Melons under Hand and Bell Glaſſes.

You muſt finiſh the firſt or ſecond week in this month, your ridges or beds for planting melons intended to be covered with hand or bell glaſſes.

Theſe ridges muſt be made with new horſe dung, prepared as directed for making other hot beds in the two months preceding.

Let the ridges be at leaſt a yard broad, four feet will not be too much; and full two feet thick of dung, ſhaken in equally, and well beat down with the fork.

If you intend to make two or more of theſe ridges, let the interval or ſpace between them be four feet wide. Theſe ſpaces or alleys ſhould, in about a month or five weeks after, be filled with dung and earth; for this will greatly aſſiſt the ſetting of the fruit.

When your ridges are ready, cover them with rich earth, well broken with the ſpade, ten inches thick; mark out the holes for the plants, four feet diſtance from one another; and ſet a bell or hand glaſs over each, keeping the glaſſes cloſe down till the earth under them is warm.

The ridges being thus prepared, bring the plants; and if they are in pots, turn them carefully out, with the ball of earth entire; make a hole in the ground where each glaſs ſtood, and place in each hole one pot of plants, with the ball of earth entire. Cloſe the earth well about the ball, and alſo about the ſtems of the plants; pour about a quart of water into each hole, and put on the glaſſes.

During the firſt two or three days, the plants muſt be ſhaded from the ſun, from eight in the morning till about four in the afternoon; but after that time let them have more and more ſun every day, till they are able to bear it fully without flagging.

Remember to lift up the warmer ſide of the glaſſes every day, to give the plants freſh air; but ſhut them cloſe down every night; and during this month, cover them with mats.

If any of the melon plants have filled the glaſſes, let the vines have liberty, about the latter end of the month, to run from under them; but they muſt not be truſted out before that time.

In order to this let each glaſs be raiſed upon props about three inches and a half high, and the ends of the vines laid out, and pegged down, at regular diſtances from one another.

But remember to cover the ridges with mats every night for fourteen or fifteen days at leaſt, after they are laid out from the glaſſes.

Gourds and Pumpkins.

The gourds and pumpkins which were ſown on a hot-bed in April, ſhould be planted out about the middle of this month, provided the weather be warm.

Remember to plant the orange, and other ſmall gourds near a wall, or other fence and when the plants begin to ſhoot, let their vines or runners be neatly trained, and faſtened up cloſe to the wall, pales, &c. By this means the plants, together with their fruit, will make a very agreeable appearance, during the months of July, Auguſt, and September.

If you have not the conveniency of a wall, or other fence, you may ſupport theſe plants with ſticks, in the following manner: Let a tall firm ſtake be fixed in the ground near each plant; and, in proportion as their vines advance in length, let them be trained up carefully round the ſtakes.

But pumpkins, and the larger kinds of gourds, ſhould be planted out in an open ſpot of ground, eight or ten feet from one another; for the vines of theſe ſorts muſt run upon the ground; and where there is room, they will extend themſelves to a very conſiderable diſtance.

Sow Gourds and Pumpkins.

It is not yet too late to ſow the ſeeds of gourds and pumpkins; but the ſooner it is done the better.

The ſeeds muſt be ſown in a hot-bed; a cucumber or melon bed already made, will anſwer the purpoſe. But if this cannot be ſpared, ſhake up two or three barrows of freſh horſe-dung into a bed about thirty inches ſquare; and cover it four or five inches thick with rich earth. Sow the ſeeds, and cover the bed with a large hand or bell glaſs.

As ſoon as the plants appear, let the ſunny ſide of the glaſs be raiſed a little every day with a prop, to give the plants freſh air; and let them be often refreſhed with water.

About the latter end of this month, or the beginning of June, the plants will have acquired rough leaves, near two inches broad, when they ſhould be planted out in the open ground, eight or ten feet from one another.

Kidney-Beans.

A full crop of kidney-beans ſhould now be planted, to ſucceed thoſe ſet in April.

The beſt and moſt profitable for this plantation are the ſpeckled, and the Canterbury white dwarf ſort; though any of the dwarf kinds will ſucceed.

They ſhould be planted in drills two feet and a half aſunder, and the beans laid two or three inches apart in the drills. Draw the earth evenly over them; and, when all are planted, let the ſurface of the ground be lightly and neatly raked.

Any of the running kinds of kidney-beans may alſo now be planted.

Theſe are all in general ſurprizing bearers, and therefore very profitable for a family, eſpecially the ſcarlet flowering bean. There is likewiſe another kind, which differs in nothing from the ſcarlet, except in the colour of its flowers, which is white; but when fit to gather for the table cannot be diſtinguiſhed from the ſcarlet, either in taſte or manner of growth. Either of theſe, or any of the large white running kinds, are very proper for this plantation.

But you muſt remember that theſe, or any of the climbing kinds of kidney-beans, require more room to grow than the dwarf ſorts. The drills therefore for theſe ſhould be three feet and a half aſunder, the beans placed five or ſix inches apart in the drills, and covered equally with earth about an inch and a half deep.

As ſoon as the plants are come up, and begin to puſh their runners, let ſome tall ſticks or poles be placed to each row, for the plants to climb upon. The runners will ſoon take hold of the ſticks, and twine themſelves very naturally round them, to the height of eight

eight or ten feet, provided the ſticks are of that height.

You will derive great advantage by planting theſe runners at this ſeaſon; for they will continue bearing till the cold weather deſtroys the plants.

But if you cannot procure the ſticks or poles, the dwarf kinds ſhould be planted; for the runners will not ſucceed without them.

Sow Lettuce Seed.

The ſeed of lettuce ſhould be ſown at two or three different times this month, that there may be a conſtant ſupply of theſe plants for the table.

The Coſs and Sileſia are the proper kinds to ſow now; though the brown Dutch may be ſown with ſucceſs, if required.

Remember to ſow the ſeeds in an open ſituation, and in a light, rich ſoil. Sow each ſort ſeparate, and rake in the ſeed with a light and even hand.

It will be neceſſary often to refreſh the beds where the ſeed is ſown, with water, eſpecially if the weather prove very dry; for otherwiſe the ſeed will not grow.

Tranſplant Lettuces.

The Coſs, Sileſia, and other kinds of lettuce ſown in the preceding month, ſhould be now tranſplanted.

In order to this, let a rich ſpot of ground, not too much expoſed to the ſun, be choſen for this purpoſe. Let it be dug about a ſpade deep, the ſurface raked very ſmooth, and the plants removed to it in the evening.

They muſt be planted in rows ten or twelve inches aſunder, and at the ſame diſtance between the plants. As ſoon as they are ſet, give them ſome water to ſettle the earth about their roots.

Small Salleting.

Let the ſeeds of creſſes, muſtard, raddiſh, rape, and other ſmall ſallet herbs, be ſown often; every five or ſix days at leaſt, if a conſtant ſupply be wanted.

If the weather be hot and dry, theſe ſeeds muſt now be ſown in a ſhady border, where the ground is rich and light. Draw ſhallow drills for this purpoſe, ſow the ſeed in them tolerably thick, and cover them lightly with earth. Remember to let them have a little water every other day in dry weather.

Turneps.

Let more turnep ſeed be ſown now: the roots will come in a very acceptable ſeaſon; for they will be fit for the table by the middle or latter end of July, and continue good for a long time.

But remember not to ſow the ſeed in hot dry weather, for it will not then ſucceed. The proper time for ſowing turneps, and all ſmall ſeeds of that kind, is when the weather is ſhowery; for then there is no fear of its growing.

Let the ſeed be ſown equally pretty thick, and on an open ſpot of light ground. Take care alſo to rake it in lightly and regularly.

Thoſe turneps which were ſown the former month ſhould now be thinned regularly, allowing ſeven or eight inches between plant and plant; obſerving, at the ſame time, to cut up all the weeds.

Spinnage.

It is not yet too late to ſow ſpinnage, for it will yet ſucceed tolerably well, if ſown in an open ſituation.

And if a ſucceſſion of this plant be required, a little of the ſeed muſt be ſown every twelve or fourteen days.

With regard to the ſpinnage ſown the preceding month, it muſt now be hoed and thinned, leaving the plants about five inches aſunder, and cutting down all the weeds under the ſurface.

Sow Carrots.

You may ſtill ſow carrot ſeed where it is required; it will grow freely, and the plants will appear ſoon, and be ready for the table by the latter end of July, or the beginning of Auguſt.

Dreſs the Beds of Carrots and Parſneps.

The beds of carrots and parſneps ſown in the foregoing months, will now be advanced conſiderably in their growth, and ſhould therefore be properly encouraged.

Let them therefore be cleared from weeds, and the plants ſeparated to a proper diſtance from one another.

The ſmall hoe is the beſt and moſt expeditious inſtrument for this purpoſe; for it will not only effectually deſtroy the weeds, and ſuch plants as are thought improper to ſtand, but alſo greatly promote the growth of the remainder, by looſening the ſurface of the ground.

If you cannot uſe the ſmall hoe, the work muſt be done by hand, or the common hoe; for the plants muſt, at any rate, be thinned out to proper diſtances, that they may have room ſufficient to grow at the top, and ſwell at the bottom.

With regard to parſneps, they muſt not ſtand cloſer than ſix or ſeven inches from one another; for their roots will be both large and ſtraight, if they have room ſufficient to expand themſelves.

Nor is this leſs neceſſary with regard to carrots; but in thinning theſe plants, the time they are intended to continue in the ground is to be conſidered.

If they are intended to be drawn young for the table, they ſhould now be thinned out to four inches aſunder; but if they are to remain till they attain their full growth, ſix or ſeven inches every way will be neceſſary.

Management of Savoys and Cabbages.

Thoſe ſavoy and cabbage plants which are intended for winter uſe, muſt be now tranſplanted.

They may be ſet between rows of early cauliflowers, or between the wider rows of garden or kidney-beans, where room is wanting. But where there is ground unoccupied by other crops, it will be much the beſt method to plant out theſe in an open ſpot by themſelves.

Let the rows, in which they are planted, be two feet aſunder, and the plants ſet eighteen inches apart in the rows. Obſerve to plant them in moiſt weather, and to give each a little water immediately after planting.

The earth muſt now be drawn up about the ſtems of early and other cabbages. This work is abſolutely neceſſary, as it will greatly ſtrengthen them, and bring them forward amazingly in their growth.

About the latter end of the month, the early plants will begin to turn their leaves for cabbaging; they ſhould therefore be aſſiſted in this operation, by tying the leaves together.

In order to this let ſome ſtrong baſs, or ſmall withys be procured, and go over the plants row by row, tying ſuch as have begun to turn their leaves pretty much inwards. But in doing this, obſerve to gather the leaves of the plant up very regularly, and then tye them together with the baſs or withy; but do not tye them too cloſe, for that will occaſion the plants to rot.

By this means the plants will be fit to uſe a fortnight at leaſt ſooner than they would be if left entirely to themſelves; at the ſame time they will be much whiter, and more tender in eating.

Sow Cauliflower Seed.

The cauliflower plants raiſed from ſeed ſown at this ſeaſon, will produce their flowers in October, and continue in great perfection the whole month of November; a ſeaſon when they will be very acceptable to moſt families.

But the ſeed ſhould not be ſown before the laſt week in this month; for otherwiſe the plants will flower too ſoon.

Let a bed of rich earth three feet wide, in an open ſituation, be prepared for this purpoſe. Let the ſeed be ſown equally, moderately thick, and lightly raked in with an even hand.

You ſhould remember to ſhade the bed every hot ſunny day, from ten to three o'clock, till the plants appear, and are all fairly come up; alſo to ſprinkle the bed often with water in dry weather.

Management of Cauliflower Plants.

Your beds of early cauliflowers muſt be often looked over carefully, about the middle and latter end of this month; for ſome of the plants will then begin to ſhew their flowers; and as ſoon as theſe appear they ſhould be ſcreened from the ſun and wet; for either of theſe would change their colour from a white to a yellow.

Remember therefore to break down three or four of the largeſt of the inner leaves over the flower, as ſoon as ever it appears in the heart of the plant.

This will anſwer the double purpoſe of ſhading the flower from the ſun, and defending it from wet. By this ſimple contrivance the flower will be preſerved in its natural whiteneſs, and at the ſame time be cloſe, firm, and beautiful.

Obſerve to water theſe plants frequently in dry weather; for this will cauſe the heads or flowers to grow to a larger ſize.

If you did not tranſplant the young cauliflowers raiſed this ſpring from ſeed, let that work be done now, and the ſooner in the month the better.

In order to this, let a piece of the richeſt ground be choſen for their reception, ſpread over it ſome good rotten dung, and dig the ground one ſpade deep, obſerving to bury the dung regularly as you proceed.

The plants muſt be ſet in this ſpot two feet, or two feet and a half aſunder every way. Remember to water them as ſoon as they are planted.

You may, if you pleaſe, ſow a crop of ſpinnage on this piece of ground, between the cauliflower plants, without doing them any great injury.

Sow Brocoli.

The ſeeds for the principal crop of both the purple and white kinds of brocoli muſt be ſown this month.

It will indeed be prudent to ſow a little of the ſeed at two different times during the month; and if a conſtant ſupply be deſired, a little of both kinds ſhould be ſown during the firſt week, and the ſecond, or principal ſowing between the fifteenth and twenty fifth of the month. For the plants raiſed from the firſt ſowing will, provided the weather be mild, be fit for the table by Chriſtmas, or a little after; while the ſecond, intended principally for ſpring uſe, will produce fine heads in February and March; and after the heads are gone, the ſtems will yield excellent ſprouts in great abundance.

Remember to ſow the ſeeds in a bed or border in an open ſituation, but not wholly expoſed to the rays of the ſun. Let each kind be ſown on a ſeparate ſpot, and the ſeeds raked in with an even hand.

Bore-cole.

Bore-cole, or, as it is often called, Scotch Kale, is a very uſeful plant, and well worth the little trouble that attends the raiſing of it. There are two ſorts of it, the brown and the green. The plants run up with very long ſtems, ſometimes three, four, or five feet high, and are ſo very hardy, that they will ſurvive the moſt ſevere winters; and in the months of February and March, their long ſtems will be loaded from the very bottom to the top with fine young ſhoots, which will boil and eat as tender as the beſt ſavoy.

The ſeed ſhould be ſown the firſt week in this month; but if you deſire the plants to grow very high, it will be better if ſown about the middle of April. But whatever time be choſen, let the ſeed be ſown on an open ſpot of good ground, and raked in lightly with an even hand. Remember to give the beds now and then a moderate watering in dry weather.

In about ſix weeks after the ſeed is ſown, the plants will be fit to plant out in the place where they are to remain.

Beans.

Let another crop of garden beans be now planted; the white bloſſom and long podded beans are the moſt proper for this ſeaſon.

If a conſtant ſucceſſion of young beans be deſired during the ſummer ſeaſon, it will be neceſſary to ſet a few at different times this month, viz. about the third, fifteenth, and twenty-ſeventh.

If you are deſirous of planting either the Windſor or Sandwich bean, let it be done at the beginning of the month, when either of theſe will often ſucceed tolerably well.

Peas.

Another crop of peas ſhould alſo be ſown now; and if a regular ſupply be wanted, let a few be ſown twice at leaſt in the month, if three times it will be the better, allowing about ten days between each ſowing.

The marrowfats will ſucceed very well, if ſown any time this month. The hotſpur kinds ſown at this ſeaſon, will ſometimes yield very good crops.

The dwarf kinds of peas generally ſucceed extremely well when ſown this month. Theſe ſeldom riſe above two or three feet high, but are excellent bearers.

The

The dwarf kinds ſhould be ſown in drills two feet aſunder, which will be room ſufficient for them.

The earth muſt now be drawn up about the ſtems of thoſe peas which were ſown in April; for this will add ſtrength to the plants, and greatly increaſe their growth.

Stick Peas.

When the peas you intend to ſtick are about ſix or ſeven inches high, the ſticks muſt be added to the rows.

Remember to let your ſticks be of a height adapted to the different ſorts of peas; and be aſſured that thoſe which have ſticks to ſupport them, will yield more than double the quantity of thoſe which have none.

Raddiſhes.

You may yet ſow raddiſh ſeed where required; but you muſt remember to water the bed frequently in dry weather, both before and after the plants appear.

Thoſe raddiſhes you intend for ſeed, muſt be tranſplanted when their roots are juſt in their prime, which will happen ſome time in the beginning of this month.

Let thoſe roots which are long, perfectly ſtraight, and whoſe tops are ſhort, be choſen for this purpoſe; and planted on an open ſpot of ground in rows two feet aſunder, and the plants eighteen inches apart in the rows. Remember to give a plentiful watering as ſoon as they are planted, to ſettle the earth about their roots.

Sow Celery.

Let the ſeed intended for a latter crop of celery be ſown the ſecond week in the month.

In order to this, let a bed of rich light earth be dug, and the ſurface laid perfectly level. When this is done, ſow the ſeeds pretty thick, and rake them lightly into the ground.

Remember to ſhade the bed from ten to three o'clock, till the plants appear; for the noon-tide rays of the ſun would otherwiſe deſtroy the ſeed.

It will alſo be neceſſary to refreſh the bed frequently with water in dry weather. And by this method the plants will be fit to be planted in trenches in Auguſt and September; and ſoon after Chriſtmas fit for the table.

Prick out Celery.

Prick out the plants of celery ſown in March from the ſeed beds, about the latter end of this month.

The bed intended for the reception of theſe plants muſt be three feet and a half broad, the earth well dug, and the ſurface laid ſmooth. When the bed is thus prepared, draw out ſome of the beſt plants from the ſeed-bed, and prick them into the other, three inches aſunder every way. Give them a gentle watering, and ſhade them from the ſun till they have taken root.

In this bed the plants are to remain till they have acquired a ſufficient degree of ſtrength, when they are to be tranſplanted into trenches, and there blanched for the table.

Sow Endive.

A little endive ſeed ſhould now be ſown for an early crop; and if a conſtant ſupply of this plant be wanted, a ſmall quantity ſhould be ſown at two different times this month; viz. about the middle and latter end.

The plants ariſing from the ſeed firſt ſown will not long continue fit for uſe, becauſe it will be apt to run to ſeed; but the plants from the ſecond ſowing will continue longer, and be fit for uſe at a very acceptable ſeaſon.

But whatever time be choſen, the ſeed ſhould be ſown pretty thick, on a ſpot of rich ground, and raked in lightly with an even hand.

Tranſplant Capſicums for Pickling.

The capſicums ſown on a hot-bed in March, ſhould be planted out in moiſt weather, about the latter end of this month.

In order to this, let a ſpot of rich ground be choſen, well dug, and the ſurface raked ſmooth and even. When the bed is thus prepared, take up the plants, and ſet them in rows a foot aſunder every way. Give them a gentle watering, and ſhade them from the ſun till they have taken root.

Tranſplant Love Apples for Soups, &c.

Abbout the middle of this month is a proper time to remove the tomatos, or love-apples, from the hot bed in which they were raiſed.

As theſe plants are very luxuriant and rambling in their growth, they ſhould be planted cloſe to ſome wall, pale, or eſpalier; and when they begin to branch out, let them be nailed to the fence in the manner of a wall-tree.

Remember to plant them againſt a wall, &c. with a ſouth aſpect, for otherwiſe the fruit will not ripen. The vacant ſpaces between the wall-trees, will be ſufficient for this purpoſe.

One ſtout plant in a place is enough. Let them be watered as ſoon as planted, and ſhaded from the ſun till they have taken root. If you ſhelter them in cold nights for the firſt fortnight after they are tranſplanted, it will be of great advantage to their growth.

Dreſs Onion Beds.

The beds of onions ſhould be now perfectly cleared from weeds, and the plants thinned out to three or four inches aſunder. Remember to leave the ſtrongeſt plants for a crop.

Hamburg Parſley, Scorzonera, and Salſafy.

Your beds of Hamburg parſley, ſcorzonera, and ſalſafy, muſt now be carefully cleared, and the plants thinned or hoed out to ſix or ſeven inches diſtance from one another.

The ſeeds of the two latter ſhould now be ſown for winter crops; for they are very apt, when ſown early, to run to ſeed, before they are hardly fit for uſe. But thoſe ſown at this ſeaſon will not run up, but be in proper order for the table by Michaelmas.

Sow Pot-Herbs, &c.

You may ſtill ſow parſley-ſeed, where it was omitted in the former months; but it muſt be done in a ſhady ſituation, where the ſun has not too great power.

At the beginning of the month a little more purſlane ſeed ſhould be ſown, that the plants may ſucceed thoſe which were ſown in April.

In order to this, make choice of a ſpot of light rich earth in the open ground; break the clods well with the ſpade, and rake the ſurface very even. Then draw

ſhallow drills about ſix inches aſunder, ſow the ſeed pretty thick in the drills, and cover it with earth. Some ſow the ſeed on the ſurface, and rake it in lightly; either method will ſucceed, for the plants will grow freely.

If coriander be wanting, this is a proper ſeaſon for ſowing a little more of the ſeed. It ſhould be ſown in the ſame manner with the purſlane, in ſhallow drills ſix inches aſunder.

Chervil ſeed will ſtill grow; if theſe plants therefore be wanted, let a little of the ſeed be ſown in ſhallow drills, and covered lightly with earth.

Plant Mint.

You may ſtill make freſh beds of mint, provided it be done the firſt or ſecond week in the month; but after that time you will find it very difficult to find a ſufficient number of good plants.

The plants muſt be about ſix or ſeven inches long, drawn up carefully with their roots to them from the old buds; and planted on a ſpot of rich ground, in rows ſix inches aſunder, and the plants four inches apart in the rows. Remember to give them a plentiful watering as ſoon as planted, to ſettle the earth about their roots.

Plant Sage, Savory, Hyſſop, &c.

The ſlips or cuttings of ſage, ſavory, hyſſop, maſtich, roſemary, lavender, may now be planted; they will grow freely.

Let ſuch ſlips as have a ſufficient degree of ſtrength, and about five, ſix, or ſeven inches long, be choſen for this purpoſe: ſtrip off the leaves, if there be any, from the bottom; twiſt that part of the ſtalk a little, and ſet them about five or ſix inches apart, and about two thirds of them into the ground.

Remember to plant them in a ſhady ſituation, and to give them now and then a moderate watering in dry weather.

Deſtroy Weeds.

A more than common degree of care will now be neceſſary, with regard to deſtroying of weeds among the crops, in every part of the garden; for weeds are at no time more pernicious than at preſent. If they are ſuffered to grow too large, they will not only exhauſt the ground, and conſequently ſtarve the plants, but alſo render the whole garden very diſagreeable. Let it, therefore, be one of the principal works to deſtroy them.

Particularly, let your crops of onions, leeks, carrots, parſneps, lettuce, and other ſmall plants that grow pretty cloſe together, be cleaned from weeds, before they begin to ſpread, and over-top the plants, which they will ſoon do, when once they begin to run.

You ſhould alſo remember that the weeds, if ſuffered to grow large among the ſmall crops, will ſo mix and entangle themſelves with one another, and likewiſe with the plants themſelves, that the work of weeding will be rendered at once extremely tedious, and extremely troubleſome.

It will indeed be otherwiſe with regard to the weeds that appear between the rows of beans, peaſe, kidney-beans, cabbages, cauliflowers, and other crops planted in rows at a diſtance from one another; for their progreſs may then be ſtopped with the greateſt eaſe; becauſe the intervals are wide enough to admit a large hoe; and with the help of ſuch an inſtrument, a perſon may go over a large piece of ground in a little time. And ſurely a taſk ſo eaſily performed ſhould not be neglected, eſpecially when it is conſidered that it will prove of the greateſt advantage to the plants.

The Nursery.

Propagate Evergreens, &c. by Layers.

This is a very proper ſeaſon for propagating ſuch evergreens, and other ſhrubs, by layers, as do not freely put out roots from any wood but the young ſhoots of the ſame ſummer's growth. The ſhoots of many ſhrubs of this kind will have attained a ſize proper for this purpoſe by the latter end of the month, and ſome of theſe ſhould therefore be then layed down.

In order to this, let ſome of the more pliant branches that afford the ſtrongeſt and beſt young ſhoots be brought down gently to the ground, and there firmly ſecured with hooked pegs. When this is done, let ſome of the young ſhoots be laid into the earth, and covered two or three inches deep with the mould, leaving about two or three inches of the top of each ſhoot out of the ground.

When they are thus laid in the ground, let a moderate watering be given them to ſettle the earth cloſely about the ſhoot, and repeated every five or ſix days in dry weather; but remember not to give them too much at one time, leſt it rot the tender fibres when they firſt ſhoot from the wood.

New Grafted and Budded Trees.

You muſt now look carefully over your new grafted and budded trees, looſening the bandages, and taking away all the clay, for there will be no further occaſion for it.

Remember not to let any ſhoots that riſe from the ſtocks below the grafts remain; but let them be rubbed off as ſoon as they appear, for they have no other tendency than to rob the graft of its nouriſhment. This care muſt be extended to the trees that were grafted the year before; for no ſhoots muſt be ſuffered to remain below the graft.

Water Seedling Plants.

If the weather prove dry at this ſeaſon, you muſt often refreſh the ſeed-beds of all young trees and ſhrubs, in general, with water.

But, at the ſame time, take care not to do it too haſtily, as the earth would by that means be waſhed away, and the tender roots of the plants would be burnt up by the rays of the ſun.

Three gentle waterings every week will be ſufficient, and prove highly advantageous to the plants.

Shade Seedling Plants.

Your ſeedling pines, cedars, cypreſſes, and other evergreens, ſhould now be ſhaded, in hot weather, from the noon-tide rays of the ſun, which will be now too powerful for them.

Water new Plantations.

If the weather proves dry, it will be neceſſary to water your ever-greens, and flowering ſhrubs, that were tranſplanted in March, once in five or ſix days, at leaſt once a week.

At the same time, let the mulch on the surface of the ground be continued over the roots of the more curious or tender kinds of these shrubs, for this will be of the utmost service, in preventing the sun from drawing away the moisture from their roots.

Destroy Weeds.

Weeding is one of the most necessary works in the nursery, at this season.

The seed-beds of all young trees and shrubs should be now carefully weeded by hand.

Nor must the weeds be suffered to grow between the rows of your young trees or shrubs. This may indeed be easily prevented, by the frequent use of a large sharp hoe; but remember to let it be done in dry days.

The Fruit-Garden.

Wall and Espalier Trees.

Your apricot, peach, nectarine, plum, cherry, apple, and pear-trees, will make strong and numerous shoots at this season; these should therefore now be properly regulated, and trained close to the wall, before they become confused.

At the same time, let all useless and ill-placed shoots be taken away. All fore-right-shoots, or such as are produced from the front of the branches, are of this kind; for they cannot, from the very nature of their situation, be properly trained in, and consequently become useless.

But all side shoots of a moderate kind and growth, and well situated for laying in, must be left, and trained in a regular order, close to the wall.

You should be particularly careful to leave as many of the well-placed shoots of apricots, peaches, nectarines, and morella cherry-trees, as can be conveniently laid in; for these trees produce the principal part of their fruit upon those shoots that are one year old; that is, those which you lay in this summer, will bear fruit the next.

A sufficient quantity therefore, of these shoots, should be now laid in, that a proper number of the best of them may be left in the winter-pruning, and the rest taken away.

Remember that these shoots must be trained very regularly, at full length, and nailed as close as possible to the wall, or espalier. They must not, on any consideration, be shortened now, for that would cause them to produce, from their sides, a number of small useless shoots, which would weaken and hurt the principal shoots, by forming too close a shade, so as to exclude the sun and air from having that free access to the fruit which is absolutely necessary to its proper growth. For though a slight shade is absolutely necessary to promote the growth of wall-fruit, yet too much of it is destructive.

At the same time, it must be observed, that this caution is not extended to those parts of the wall, or espalier, that are vacant; for there some of the adjacent young shoots must now be shortened; for by this means they will put out side or lateral shoots, to supply the vacant parts.

Thin Apricots, Peaches, &c.

If you perceive the fruit on any of the apricot, peach, or nectarine trees too thick, let some of them be now taken away.

For it should be observed, that these trees will sometimes, in favourable seasons, set three times more fruit than their roots are able to supply with nourishment; and if the whole, or even too many of them, were to be left, they would starve one another, and the fruit, in general, would be small and ill-tasted.

Nor would the mischief end with the season, it would be extended to two or three succeeding years. For the trees, from the too great quantity of fruit, would not be able to produce shoots proper for bearing fruit the next year; and, at the same time, the trees would be so much exhausted, that they would not recover strength sufficient to produce any proper wood before the second year after; consequently a tolerable crop could not be expected before the third year.

When therefore a tree is over-loaden with fruit, let them be now reduced to a moderate quantity; and the sooner this is done, the better it will be both for the tree and the remaining fruit.

Nor should this thinning be performed in a careless manner; the branches should be regularly looked over one by one, singling out the fruit you intend to leave on each branch before you take any away.

The most promising and best shaped fruit, provided they are properly situated on the branches, should be left at such distances, that each may have sufficient room to swell, and grow freely to its full bigness, every way, without touching another; five or six inches will be sufficient room for all the middling kinds of fruit.

At the same time, some regard should be had to the strength of the branches. Suppose, for instance, the bearing shoots, or branches, to be of three different sizes, strong, middling, and weakly; you may leave three of the fairest and best placed fruit on the strong, two upon the middling, and one only on the weaker branches.

If the above cautions, with regard to the distances between the fruit, and the nature of the branches, be observed in thinning the trees, they will doubtless bring each kind to its full perfection. At the same time, the trees will shoot freely, and produce a sufficient quantity of bearing wood for the succeeding year.

The smaller kinds of fruit, such as the masculine apricots, the nutmeg-peaches, and early nutmeg peaches, may be left closer to one another, and a greater number of them suffered to remain on the branches.

Four or five of them, for instance, may be left on the strong; three on the middling; and two on the weaker branches.

Vines.

At this season your vines will shoot vigorously, and send out, besides bearing, and other useful shoots, numbers of others that are altogether useless; these should therefore be taken away, and the sooner this is done the better.

Art will greatly assist nature, in ripening grapes in an unfavourable season; and this is the time for employing it.

In order to this, the vines must now be perfectly cleared from all kinds of useless shoots; and, at the same time,

time, all the fruit-bearing branches, and other well-placed useful shoots, should be nailed up regularly, and close to the wall.

This work should be done before the shoots begin to entangle, or any way interfere with one another; for very great advantages attend this early dressing and regulating the vines; nor is there any other method of bringing the bunches of these fruit to any degree of perfection, but by timely nailing in the useful shoots, and clearing the vines of such as are useless.

All the bearing shoots, that is, such as have fruit upon them now, must be left, together with such other shoots as have strength, and are well situated for training, in order to produce fruit next year.

But all weak and straggling shoots, such as rise immediately from the old wood, are useless, and must be taken away, wherever they are produced; and even strong shoots that are destitute of fruit, and that rise in places where they are not wanted, or not well placed for training in to produce fruit next year, should be displaced.

When this is done, let all the bearing shoots, together with those that are useful, and produced in proper places, be nailed, in regular order, close to the wall. Remember not to stop any of the shoots now, but let each, for the present, be trained up at its full length.

The shoots must not be nailed up promiscuously across each other, as often practised; but let every shoot be laid in straight, and clear of another, in a regular manner, so that each shoot, and every branch of fruit, may equally enjoy the advantage of the sun and free air.

After this, observe that all shoots that rise in any part of the vines must be constantly rubbed off, as soon as they appear; let not, on any account, these small shoots which commonly rise from the sides of the same summer's shoots now laid in, remain; but let these also be rubbed off, as soon as they begin to advance.

Vineyards.

The vines planted in the vineyard also require a very large share of attention. All the shoots that have fruit upon them, and others that are strong, and well placed for the service of another year, must now be trained up close and regularly to the stakes.

At the same time, the vines must be cleared from all useless wood, and also from all such shoots as are barren of fruit, or produced in such places, that they cannot be trained for the service of another year: let all these be rubbed off close.

Remember to keep the ground between the vines clear from weeds; a caution necessary to be observed during the whole summer season; for if weeds of any considerable size be suffered to grow near the vines, they will not only rob them of their nourishment, but also greatly retard the growth of the grapes, by keeping a continual chilly dampness about the vines. Let therefore the hoe be applied to them whenever they are found; but remember to do it in a dry day.

Examine the stakes that support the vines; let them be firmly fixed, and in their proper places; and that all the fruitful shoots, and others that are well situated, be neatly and securely fastened to them.

Strawberry Plants in Blossom.

If the weather prove dry this month, the strawberry plants, which will be now in full blossom, must be watered very frequently; thrice a week, at least; and let the waterings be sufficient to reach the roots of the plants. For if this necessary work be omitted, your crop of strawberries will be very little, and those that are produced small and ill-tasted.

Examine new Grafted and new Budded Trees.

Let the trees of all sorts grafted this spring be now examined; and wherever you find the graft and stock well united, take away both the clay and the bandage, for they will be then both useless.

At the same time, examine the trees that were budded last summer, and take away all the shoots that rise from the stock besides the bud; for the stock should have nothing to supply with nourishment but the bud, which will therefore shoot with more vigour.

Cleanse the Fruit-Tree Borders.

Remember to keep the borders where wall and espalier fruit-trees grow very clean from weeds, for these exhaust the nourishment, prove a harbour to slugs and insects, and give the whole an unsightly appearance.

As soon, therefore, as any weeds appear, let them be eradicated, which will be easily done with a sharp hoe; but let it be done in a dry sunny day.

Destroy Snails, Insects, &c.

Most of the wall fruits, especially peaches, nectarines, apricots, &c. are very liable to be greatly injured by snails; let the trees therefore be looked over carefully in the morning and evening, the times when these vermin leave their holes to feed upon the fruit, when they may be easily destroyed.

If you perceive your wall-trees are annoyed with any kind of insects, let them be destroyed as soon as perceived; for after they begin to attack any single branch of a tree, they will soon over-run the whole, if not prevented. The best method of destroying them is this:

Take away all the leaves that are infected with them; that is, such as are shrivelled or curled up; then strow some tobacco dust over all the branches and leaves, letting it remain there two or three days, and then wash it off, by giving the trees a thorough watering all over their branches; for if the tobacco dust was suffered to remain any longer, it would injure the trees.

A hand engine will be highly useful for watering wall-trees. For by the help of this a person may stand in the walks, and, with great ease and expedition, throw the water against any part of the trees, from the bottom to the top of the wall, even supposing it fifteen or twenty feet high; and this is by far the most easy, expeditious, and effectual method of watering these trees. For the force of the water will clear the leaves and branches from dust, cob-webs, or any other filth they may have contracted; and if these waterings are repeated now and then, in very dry weather, no insects can breed upon the trees.

Experience only can fully shew the great service that wall-trees, in general, receive from being watered in this manner all over their branches, in dry hot weather.

Water

Water new Planted Trees.

Remember to refreſh your new planted trees, whether ſtandards or dwarfs, with water, once a week at leaſt, in dry weather; and let them ſometimes be watered all over their branches. If no mulch be laid on the ſurface of the ground over their roots, they ſhould be watered moderately twice a week, in dry weather.

The PLEASURE or FLOWER-GARDEN.

Sow Ten-Week-Stocks, &c.

You may ſtill, during the firſt or ſecond week in this month, ſow ten-week-ſtocks, China aſter, and Indian pink.

A ſmall bed of rich light earth ſhould be prepared for them in the natural ground; where the plants will ſoon come up and grow freely, if often refreſhed with water, in dry weather, and ſheltered in cold nights with mats.

Sow the Seeds of hardy Annuals.

The ſeeds of ſeveral of the ſorts of annual plants, particularly lupines, ſweet ſultan, flos Adonis, white and purple candy-tuft, lobels, catch-fly, dwarf lychnis, dwarf poppy, Virginia ſtock, Venus navelwort and Venus looking-glaſs, ſnails, caterpillars, dwarf annual ſun-flower, lavetera, oriental mallow, naſturtiums, convolvulus major and minor, Tangier and ſweet-ſcented peas, may be ſtill ſown in the borders with ſucceſs.

But remember to ſow them in ſmall patches, in the places where you would have them flower; for none of theſe ſorts ſucceed after being tranſplanted. Remember alſo to ſprinkle frequently with water the patches where they are ſown, in dry weather.

Sow Perennial Flower Seeds.

The ſeeds of ſtock july-flowers, ſweet-williams, columbines, carnations, pinks, ſcabiuſes, Canterbury-bells, pyramidal bell-flowers, holly-hocks, French honey-ſuckles, and ſome others, may ſtill be ſown with ſucceſs, provided it be done the firſt or ſecond week in the month.

Let a ſpot of light rich ground, not too much expoſed to the ſun, be choſen for theſe ſeeds; break the earth well as you dig it, and divide the bed into as many parts as you intend to ſow different kinds of ſeed.

When the bed is thus prepared and divided, let the ſeeds be ſown as equally as poſſible, and raked in with even hand. Or, which perhaps is a better method, draw off about an inch deep of earth from the ſurface, with the back of the rake, into the alleys, and then ſcatter the ſeed equally on the bed. This being done, draw the earth that was turned off the bed, in an even manner over the ſeed, and lightly ſmooth the ſurface with a rake.

By purſuing this method the plants will come up ſtrong, and produce abundance of flowers next month.

Tranſplant Biennial and Perennial Flower-plants.

Moſt of the biennial and perennial flower-plants ſown in March will be fit for tranſplanting about the third week in the month; particularly the wall-flowers, ſtock july-flowers, columbines, ſweet-williams, ſingle ſcarlet lychnis, roſe campion, and catch-fly. Thoſe alſo which were ſown early in the ſpring, as Canterbury-bells, Greek valerian, tree-primroſe, fox-gloves, French honeyſuckles, and holly-hocks, may be tranſplanted about the latter end of this month.

But remember that they muſt be removed into nurſery beds, in order to get ſtrength, before they are planted out for good.

In order to this, let a ſpot of good clean ground be dug, raked very even, and divided into beds three feet and a half broad.

When this is done let the plants be ſet in rows, ſix inches every way from one another, and each ſort ſeparate. As ſoon as they are planted, let them be moderately watered to ſettle the earth about their roots.

In theſe nurſery beds they are to remain till September or October, when they muſt be planted out where they are to remain. They will flower, and make a very elegant appearance next ſummer.

Remove hardy Annual Plants.

The more hardy annual plants, as the African and French marigolds, chryſanthemums, marvel of Peru, China aſter, Indian pink, ten-week-ſtock, perſicarias, the common kinds of balſams, capſicums, and magnonette; purple amaranthuſes, ſcabiuſes, egg-plants, and love-apples, may, about the middle of the month, be removed into the natural ground.

Theſe will, if planted out into the beds, borders, and other parts of the flower-garden, make a very fine appearance about two months hence.

Remember to chuſe a ſhowery time for ſetting theſe flowers; for if this be done in dry hot weather, not one in ten of the plants would ſucceed; about four or five o'clock in the evening is the moſt proper time for planting them.

You ſhould alſo be careful when you ſet them to mix the different ſorts, ſo that there may be a variety of flowers in every part.

They ſhould be moderately watered as ſoon as planted, and the operation repeated every other evening till the plants have taken root.

Propagate Perennial Fibrous-rooted Plants.

The latter end of this month is a proper ſeaſon for propagating perennial fibrous-rooted plants by cuttings of the young flower-ſtalks. The double ſcarlet lychnis, lychnidea, double-rockets, ſtarwort, or the late flowering aſters, and many others of that kind, will ſucceed very well. The method is this:

Let ſome of the young flower-ſtalks be cut off cloſe, and divided into proper lengths, each length having three or four joints.

They muſt be planted in a ſhady border of light rich earth, about four inches aſunder, and two of the joints put into the ground, leaving the reſt above the ſurface. Cloſe the earth well about them, and give them a moderate watering.

Propagate double Wall-Flowers.

The only method of propagating the true double kinds of wall-flowers is by ſlips.

Theſe ſlips muſt have ſome ſtrength, and be from three to ſix inches long. Let theſe be ſlipped off carefully from

from the mother plant in a moiſt or cloudy day; and the leaves from the bottom to ſomething more than half way up the ſlips taken away, ſo that there may be two or three inches of clear ſtalk.

Twiſt the ſtalks a little at the bottom, and plant them up to the leaves in a ſhady border, about four or five inches aſunder, giving them a moderate watering.

By the end of September they will be well rooted, provided they are often refreſhed with moderate waterings in dry weather, when they may be taken up and planted in pots.

Carnations.

You ſhould now be careful to give your carnation plants in pots every aſſiſtance in the power of art, in order to encourage them to ſhoot vigorouſly.

Sticks ſhould be placed to ſupport the flower-ſtalks, which will now ſhoot apace, provided they were not placed there laſt month. Be ſure to let the ſticks be ſtraight, and of a ſufficient length. Thruſt them into the ground as cloſe as poſſible to the plant, and tie the flower-ſtalk neatly to them in different parts.

If you perceive any decayed leaves about the plant take them away, ſtir the ſurface of the mould a little, and add a ſprinkling of fine freſh earth over it; bind it cloſe up about the plants, and immediately give the whole a moderate watering.

If you are deſirous of having large and handſome flowers, all pods which riſe from the ſides of the ſtalks, ſhould now be taken off, leaving none but the top buds.

Remember to ſhade your pots from the mid-day ſun, and to water your plants every two or three days in dry weather.

Hyacinths, Tulips, &c.

Your beds of curious hyacinths, tulips, ranunculuſes, and anemonies, which are now in full bloom, muſt be defended from the mid-day ſun; and alſo ſheltered from heavy rains, by means of hoops and mats, as directed in the former month.

The mats ſhould be drawn over the hoops every day, when the ſun ſhines, about nine or ten in the morning, and removed about four or five in the afternoon.

By this means the flowers will be preſerved a conſiderable time in their full beauty; a fortnight at leaſt longer, than if they were fully expoſed to the ſun and heavy ſhowers of rain.

But remember to let your hoops be of a proper height; for otherwiſe the flower-ſtalks would be drawn up weak, and, in conſequence of that weakneſs, the colours of the flowers would be faint.

Autumnal flowering Bulbous Roots.

The leaves of ſuch bulbous roots as blow in autumn will now be withered, and when this happens they ſhould be taken out of the ground.

Remember to do this in dry weather, and to ſeparate the ſmall off-ſets from the main root. When this is done, ſpread the roots upon a mat in the ſhade to dry; after which they are to be put up till about the laſt week in July, and then replanted.

Auriculas.

The pots of your auricula plants ſhould, as the flowers fade, be immediately removed off the ſtand or ſtage, and placed upon a clean level ſpot where the plants can enjoy the morning ſun freely, till nine or ten o'clock, but no longer. In this ſituation they are to remain till Auguſt.

Remember to keep both the pots and ground where they ſtand perfectly free from weeds; and whenever any decayed leaves appear on any part of the plants, let them be taken away immediately, and the pots often refreſhed with water in dry weather.

Your tubs or boxes of ſeedling auriculas muſt now be removed to a ſhady place, if not done before: the place muſt be open to the morning ſun only.

They muſt be frequently ſprinkled with water in dry weather, and kept entirely free from weeds.

Climbing Annual Plants.

Your naſturtiums, convolvulus major, ſweet-ſcented and Tangier peas, and others of the climbing kind, will now require ſupport. Let ſticks therefore be placed for them to climb upon as ſoon as they begin to run.

Graſs and Gravel Walks.

You muſt now mow your lawns and graſs walks often, at leaſt once a week, if you intend to keep them in any tolerable order.

Your gravel walks ſhould be duly rolled, eſpecially after ſhowers of rain; for this will make the body of the walk firm, and render the ſurface very cloſe and ſmooth. If any weeds appear let them be immediately picked out, and no kind of litter ſeen upon them.

Deſtroy Weeds.

If you do not remember to deſtroy the weeds as ſoon as they appear, they will preſently get a head, for they now grow very faſt.

Let it therefore be a conſtant rule to cut them off as ſoon as they appear, either by the hand or hoe. If the latter be uſed, let it be done in dry weather, and the ground neatly raked after the operation, to draw the weeds and other litter from the ſurface.

JUNE.

Work to be done in the KITCHEN-GARDEN.

Cucumbers in Frames.

YOUR cucumber plants in frames muſt now be well ſupplied with water and freſh air.

In hot weather the plants ſhould be watered every two or three days; the beſt times for doing it, are about ſeven or eight o'clock in the morning, or four or five in the afternoon.

Let the lights be tilted up a conſiderable height every day, to give the plants a ſufficient quantity of freſh air; but it will be adviſeable to ſhut the lights down every night, at leaſt till the latter end of the month.

About that time alſo it will be proper to raiſe the frame high enough to let the plants run out from under it,

Cucumbers,

Cucumbers under Bell-glaſſes.

The cucumber plants under hand or bell-glaſſes, muſt now be ſuffered to run freely from under them.

Each glaſs ſhould therefore be raiſed upon three or four props, and the vines or runners of the plants be trained out with care and regularity.

They will alſo require a moderate watering three times a week in dry weather.

Pickling Cucumbers.

The cucumber plants ſown the latter end of laſt month in the natural ground for picklers, ſhould now be thinned. Remember to do it as ſoon as the rough leaf in the heart of the plants begins to appear.

Four at leaſt of the ſtrongeſt plants, but never more than five or ſix, ſhould be left in each hole; the reſt ſhould be carefully drawn out, and all the weeds on the whole ſpot cleared away.

The earth muſt be drawn up to the ſhanks of the remaining plants within a little of the ſeed leaves, and a light watering given to each hole to ſettle the earth. The plants after this will get ſtrength, and grow ſurprizingly.

Remember to refreſh them often with water; if the weather be very dry, let it be done every other day.

Sow Cucumbers.

You may ſtill ſow cucumber ſeed where required; at leaſt any time before the fifteenth of the month.

The plants from this ſowing will ſoon come up, begin bearing about the middle of Auguſt, and yield plenty of fruit during the remaining part of that month, and the greater part of September.

Melons in Frames.

You muſt ſtill ſhade, during the middle of the day when the ſun ſhines, the melon plants in frames.

This muſt be particularly remembered when the earth is but ſhallow upon the beds, or where the plants lie very near the glaſſes; for if they are in either of theſe caſes, expoſed to the full rays of the noontide ſun, the leaves will be ſcorched, and the juices of the vines, roots, and young fruit exhauſted. Even thoſe that have ſwelled to a tolerable ſize, would, for want of proper nouriſhment, be greatly checked, and become at once ſtunted and ill ſhaped.

Let therefore ſome thin mats be ſpread over the glaſſes every day when the ſun ſhines warm; but this need not be done before eleven o'clock; and the mats may be removed by two.

The thinner the mats uſed for this purpoſe are, the better, for the plants ſhould not be darkened by too full a ſhade; nothing more is required than to take off part of the ſun's rays, which will have the greateſt tendency to promote the growth of this fruit, whatever be the ſize.

Remember to give the plants a conſtant ſupply of freſh air every day, by tilting the lights at the back of the frame to a conſiderable height.

Frequent refreſhments of water will alſo be very ſerviceable to thoſe plants at this ſeaſon of the year, eſpecially if the beds where they grow have but a ſhallow depth of earth.

In that caſe the plants will, in hot weather, require to be moderately watered once a week; but care ſhould be taken in doing this, to give very little water near the ſtem or head of the plants.

But where the beds are twelve or fifteen inches thick, and the earth of a loamy conſiſtence, a very little water will be ſufficient.

Melons under Bell-glaſſes.

You muſt now give your melons under bell-glaſſes free liberty to run out.

In order to which each glaſs ſhould be raiſed and ſupported upon three props about two or three inches high; and the vines be laid out in a careful and regular manner.

It will be prudent to cover them every night with mats till about the middle or towards the latter end of the month, when the covering may be entirely laid aſide, unleſs the weather ſhould prove very wet; and in that caſe the plants ſhould be covered occaſionally.

For it ſhould be remembered that nothing is more prejudicial to theſe plants than too much wet; for this not only chills the young fruit, and prevents their ſetting and ſwelling, but alſo periſhes many of the roots of the plants.

When therefore the weather happens at any time to be very rainy, it will be proper to defend theſe plants as much as poſſible from it; and this may be done effectually by a covering of good thick mats, or canvaſs, ſupported by hoops fixed acroſs the bed.

Fill up the Alleys between the Melon Ridges.

It is now time to fill up the alleys between the melon ridges, that the roots of the plants may have ground ſufficient to extend themſelves.

Theſe alleys, if the beds are made wholly or a great part above the ground, muſt be filled up with dung, and covered with a proper thickneſs of earth.

If new hot-dung was uſed for this purpoſe, it would be of great advantage, as it would throw a freſh heat into the beds, which would greatly promote the ſetting and ſwelling of the fruit.

The dung muſt be firſt laid in, and trod firmly down, raiſing it full as high as the dung of the beds; and then covering it with earth, till the interval be in a direct level with the ſurface of the beds.

Cauliflowers.

The cauliflowers ſown in May ſhould be pricked out into a nurſery bed of rich earth, about the latter end of this month.

In order to this, let a bed about three feet and a half broad, in an open ſituation, be prepared for their reception. Then prick in the plants about three inches aſunder, and give them a little water to ſettle the earth well about their roots; ſhade them from the ſun till they have taken root, and, if the weather be dry, give them a little water occaſionally.

In this bed the plants are to remain a month, in order to get ſtrength, when they are to be planted out for good in the place where they are to produce their flowers.

Remember to look over your plantations of early cauliflowers now and then, in order to break down ſome of the inner leaves over the young heads as they appear.

Turneps.

A full crop of turneps for uſe in autumn ſhould be ſown ſome time this month.

But let it be done, if poſſible, in a dripping time; or, at leaſt, when there is a proſpect of rain falling ſoon after. Remember to ſow the ſeed equally, and rake it in carefully with an even hand, as ſoon as ſown.

The crop of turneps ſown in May will now require hoeing, and the plants to be thinned in a regular manner.

You ſhould remember to begin this work as ſoon as the turneps have gotten rough leaves about an inch broad; for then the work may be done with expedition and regularity, and prove of the greateſt advantage to the growth of the plants.

Remember to leave the plants about eight inches from one another.

Carrots and Parſneps.

The crops of carrots and parſneps muſt now be cleared from weeds; and the plants, where they ſtand too thick, thinned out to proper diſtances, that their roots may have ſufficient room to grow. About ſix or eight inches diſtance between plant and plant will be ſufficient.

It ſhould be remembered, that the above diſtance is intended for thoſe roots which are deſigned to grow to their full ſize; for with regard to thoſe beds of carrots which are intended to be drawn while young, four or five inches will be a ſufficient diſtance between them.

Kidney-Beans.

Let another crop of kidney-beans be now planted, to ſucceed thoſe planted laſt month.

Either the dwarf or climbing kinds of kidney beans, may now be planted. But the running kinds ſhould be planted the firſt or ſecond week in the month; for they do not ſucceed ſo well if planted later.

The beſt ſorts for this purpoſe are the white Dutch, the ſcarlet bloſſom, and the large white kind; all theſe are exceeding good bearers, and equal to any for eating.

Remember in planting any kinds of kidney-beans to allow them ſufficient room; that is, let the drills for the running kinds be at leaſt three feet and a half, or four feet aſunder; and the diſtance between the drills for the dwarf kinds not leſs than two feet and a half.

If the ground be very dry at this ſeaſon, it will be proper to water the drills well before you put in the beans; for this will make them riſe much ſooner, and with more regularity.

Let the earth be drawn up to the ſtems of thoſe kidney-beans which were planted laſt month; this will ſtrengthen the plants, and aſſiſt them greatly in their growth.

Sticks ſhould alſo be placed to the running kinds of kidney-beans, which were planted at the beginning of laſt month. This ſhould indeed be done as ſoon as the plants ſend forth their runners, for they will then catch the ſticks readily.

Peas and Beans.

You may ſtill ſow peas, and plant beans, if the ſeaſon prove moiſt, but, otherwiſe, they will not ſucceed.

The ſmall kinds of beans are moſt proper for planting now; none better than the white-bloſſom and mazagan. Theſe will often yield plentiful crops at Michaelmas.

But the larger kinds of peas, as the marrow-fats, &c. will beſt anſwer your purpoſe; though a few of the beſt ſorts of hot-ſpurs ſhould be alſo ſown.

If the weather and ground be very dry, let both your peas and beans be ſoaked eight or ten hours in pond or river water; and then ſown or planted immediately.

Remember to allow ſufficient room between the rows; for the ſucceſs greatly depends upon that particular.

Savoys and Cabbages.

This is the proper ſeaſon for planting a full crop of ſavoys and cabbages for winter uſe.

The plants ſhould be ſet in rows, two feet aſunder, and eighteen or twenty inches apart from one another in the rows.

Some gardeners, where ground is very ſcarce and dear, ſet the ſavoy and cabbage plants between the rows of forward beans, early cauliflowers, and other crops of that kind, the rows of which are at a conſiderable diſtance from one another, and which will ſoon be off the ground. The plants will ſucceed by this method, nearly as well as if planted on a piece of freſh ground.

Broccoli.

The young broccoli plants ſown in May muſt now be pricked out from the ſeed bed.

In order to this, let a piece of good mellow ground be dug, and the ſurface well raked. In this bed let the plants be ſet, about three or four inches aſunder every way. Let them be watered immediately, and the operation repeated occaſionally in dry weather.

In this bed they are to remain a month or five weeks, and then to be planted out for good.

More broccoli ſeed ſhould be ſown about the ſecond week in the month; and the plants from this ſowing, will produce good heads about the beginning of March.

Brown Cole.

The plants brown or bore-cole ſown in April or the beginning of laſt month, muſt be now pricked from the ſeed bed into a nurſery bed, at the diſtance of four inches aſunder every way. In this bed they are to remain till they have gathered ſtrength, which will be in about a month, when they are to be planted out where they are to remain.

Onions.

Remember to keep your onion beds free from weeds; and whenever you perceive the plants too thick, let them be properly thinned: they ſhould not ſtand nearer together than four or five inches.

But be careful in thinning your onions to leave the moſt promiſing plants behind, taking away thoſe which are ſmall and ſtunted.

Leeks.

About the third or fourth week in the month, your leeks will be grown to a proper ſize for tranſplanting.

Let therefore a piece of ground in an open ſituation be prepared for that purpoſe, and the plants ſet in rows eight inches aſunder, and about ſix inches from one another in the rows.

Celery.

The celery ſown early laſt month, will about the middle of this be fit for blanching.

In

In order to this, let a piece of rich ground, in an open ſituation, be choſen; and there mark out the trenches by a line, about a foot wide, allowing an interval of three feet between the trenches.

Let each trench be dug about ſeven or eight inches deep, laying the earth taken out equally on each ſide; then lay very rotten dung about two or three inches thick at the bottom of each trench, and dig the bottom neatly, burying the dung equally three or four inches deep.

The trenches being thus prepared, ſet the plants in a ſingle row, exactly in the middle of the trench, about five inches aſunder. As ſoon as they are planted, give them a little water, and repeat the operation occaſionally till they have taken root.

In about a month or five weeks after the plants are ſet in the trenches, they will require to be earthed up, in order to render the ſtalks white and tender.

In order to this, the earth laid on the ſides of the trenches muſt be broken ſmall, and care taken to lay it gently to both ſides of the plants, and not to earth them too high at firſt, leſt you bury their hearts.

Remember to perform this work in dry weather, and, after you begin, to repeat it every fortnight or three weeks, till the plants are fit for the table.

Endive.

About the middle or towards the latter end of the month, ſome of the firſt ſown plants will be ready for blanching.

Let therefore an open ſpot of ground be dug one ſpade deep, and the ſurface raked ſmooth.

In this bed let the endive plants be ſet in rows about a foot aſunder every way, and ſome water given them immediately.

The main autumn crop of endive ſhould be ſown about the latter end of the month, in an open ſpot of ground, and the ſeed raked in equally with an even hand.

But if a conſtant ſupply of that vegetable be deſired, a little of the ſeed ſhould be ſown at two different times this month, in the ſame manner as mentioned above for the autumn crop.

Lettuces.

It is now time to remove your lettuce plants ſown in May from the ſeed-bed into an open ſpot of good ground.

But remember to do it in moiſt ſhowery weather, for they will not ſucceed in a dry ſeaſon; unleſs you plant them in drills about a foot from one another, and water them as ſoon as planted, repeating the operation frequently. For the drills will retain the water much longer than the level ground, and conſequently aſſiſt the plants in their growth.

You ſhould alſo ſow ſome Coſs, Sileſia, and brown Dutch lettuce ſeed to ſupply the table in Auguſt and September.

Creſſes, Muſtard, &c.

Let a little of the ſeed of creſſes, muſtard, and other ſmall ſalletting, be ſown every week at leaſt.

But remember to ſow it in the ſhade, and to refreſh the bed often with water in dry weather, both before and after the plants appear.

Baſſmint, &c.

This is a proper ſeaſon for gathering mint, and other plants that are in flower, for drying or diſtillation.

Remember to do it in a dry day, and when firſt the plants begin to flower; for they are then in the greateſt perfection.

As ſoon as the plants are cut, let them be ſpread or hung up in ſmall bundles, in a light airy room, out of the reach of the ſun's rays, where they may dry gently. None of theſe muſt ever be laid in the ſun to dry; for the greater part of their virtues would by this means be exhauſted, and the plants rendered almoſt uſeleſs.

Pepper-mint for diſtilling ſhould alſo be cut this month, provided the plants are in flower; but if not, let them continue till the next.

Remember to cut them in a dry day, and to let the plants be dried in the ſhade.

Planting Pot-Herbs, and other Aromatic Plants.

Your young plants of thyme, ſavory, ſweet marjoram, and hyſſop, will be ready to remove for the ſeed-bed about the latter end of the month, provided the weather be ſhowery.

Let therefore a piece of ground be dug for this purpoſe, the ſurface raked ſmooth, and divided into beds three feet and a half broad.

In theſe beds let the young plants be ſet by a line, about ſix or eight inches aſunder every way; and let them have a little water as ſoon as planted.

Burnet, borage, clary, marigold, and other herbs of that kind, ſown in the ſpring, ſhould now be planted out.

Slips or cuttings of thyme, ſavory, hyſſop, ſage, lavender, lavender cotton, rue, roſemary, and ſouthernwood, may ſtill be planted if required; for they will ſucceed in general, if planted in a ſhady ſituation, and now and then moderately watered.

Cardoons.

You muſt now remove your cardoons into the place where they are to blanch.

Remember to allow theſe plants a pretty deal of room, that they may be conveniently earthed up to a proper height.

In order to this, let a ſpot of the beſt ground, in an open ſituation, be choſen for them. In this ſpot plant the cardoons in rows a yard and a half aſunder, keeping the ſame diſtance between the plants in each row. Dig no trench, but plant them on the level ground, water them as ſoon as planted, and repeat the operation till they have taken root.

Watering in general.

All plants in general, which have been lately removed, ſhould be watered in dry weather, and the operation duly performed till have taken root.

The NURSERY.

Inoculate Peaches, Apricots, and Nectarines.

You may begin about the middle of this month, to inoculate apricots, and the early kind of peaches and nectarines.

Experience has abundantly ſhown that the above trees generally ſucceed beſt when budded upon plum ſtocks. The ſtocks ſhould be raiſed from the ſtones; and when they are two or three years old, they will be of a ſize proper for budding.

Remember that the cuttings from whence the buds are to be taken be cut from healthy trees, ſuch as ſhoot moderately free, and of the ſame year's growth. This being obſerved, the operation is performed in the following manner:

Having provided yourſelf with proper cuttings, a ſufficient quantity of new baſs mat for bandages, and a ſharp penknife, with a flat ivory haft ſomewhat taper, and quite thin at the end; make a croſs cut with your knife in the rind in the middle of the ſtock, remembering to make the cut no deeper than the bark; then from the middle of the croſs cut, let another be made downwards, about two inches in length, ſo that the two cuts together may form a T.

When this is done, take one of your cuttings or ſhoots, and take off the bud as follows:

Begin at the lower or larger end of the ſhoot, and cut off all the leaves from it, but let the ſtalks of them continue; then about half an inch or a little more below the ſaid eye or bud, make a croſs cut in the ſhoot, and placing your knife about the ſame diſtance above the eye, cut off the bud, together with part of the wood. Separate immediately that part of the wood which was taken off with the bud, by placing the point of your knife between the bark and the wood at one end, and pulling off the woody part, which will part readily from the bark. This being done, examine immediately the inſide of the bud to ſee if the eye be left; for if there appear a ſmall hole, the eye is gone with the wood, and therefore uſeleſs; but if there be no hole, the bud is good, and is to be immediately inſerted in the ſtock; obſerving, for the reception of the bud, to raiſe gently, with the haft of your knife, the bark of the ſtock downwards on each ſide, from the croſs cut, and directly thruſt the bud gently in between the bark and the wood, placing it as ſmooth as poſſible; and obſerving if the bud be too long for the inciſion in the bark of the ſtock, to ſhorten it ſo as to make it ſlip in readily, and lie perfectly cloſe in every part.

When the bud is thus fixed, let the ſtock in that part be immediately bound round with a ſtring of baſs mat, beginning a little below the cut, and proceeding upwards, drawing it cloſely round to the top; but be ſure to miſs the eye of the bud, bringing the tying cloſe to it both below and above, leaving only the very eye itſelf open.

About three weeks or a month after inoculation is performed, the bud will have taken with the ſtock, which may be known by the bud appearing plump, while thoſe which have not will look black, and be decayed. Let therefore the bandages of thoſe which have taken be looſened, that the ſap may have free courſe to the bud; for were the bandages ſuffered to remain as firſt tyed, they would pinch and ſpoil the buds. To prevent this, therefore, all the bandages ſhould be looſened in about three weeks, or a month at fartheſt after the operation.

Nothing more will be now neceſſary till the beginning of next March, when the head of the ſtock is to be cut off about a hand's breadth above the bud. The part above the bud is left to faſten the ſhoot to, which the bud makes next ſummer; for the buds never begin to ſhoot till the ſpring after budding. But the autumn following it ſhould be cut off cloſe, juſt above the bud, that the place of amputation may be the more readily barked over.

The general ſeaſon to bud or inoculate is from about the middle of June till about the ſame time in Auguſt, according to the forwardneſs of the different ſort of trees intended to be budded. This may be eaſily known by trying the buds; for when they will readily part from the wood, as already mentioned, it is then the proper ſeaſon for budding that kind of fruit.

You ſhould remember to perform this operation in moiſt cloudy weather, as the bud and ſtock being then more replete with juices than in hot dry weather, they will more readily unite.

Examine the Trees that were Budded laſt Year.

The trees which were budded laſt year will now have made vigorous ſhoots, which muſt be ſupported.

In order to this, it will be proper to provide yourſelf with ſtakes about two feet long, driving one of them into the ground cloſe to the ſtock of each tree that has made a vigorous ſhoot, and tye the ſhoot to the ſtake at two different places. This will effectually prevent its being broken or ſeparated from the ſtock by the wind.

Look over your Grafted Trees.

Examine your grafts; and where you perceive they have made vigorous ſhoots, let them be ſupported by tying them to ſtakes driven into the ground near the ſtocks.

Propagate hardy Exotic Trees and Shrubs.

Layers may be now made from many of the hardy exotic trees and ſhrubs, eſpecially thoſe of the evergreen kind.

But you muſt remember that only the ſhoots of the ſame ſummer's growth are now to be layed. The operation is performed in the following manner:

Having fixed on the plant, let ſuch branches as are furniſhed well with young wood, be brought down gently to the ground, and there ſecured with hooked ſticks. This being done, let all the young ſhoots on each branch be laid, covering them two or three inches deep with earth; but leave at leaſt two or three inches of the top of each ſhoot out of the ground.

Remember to keep the earth about the layers moiſt, but not wet; and if this be duly obſerved, many of them will be well rooted by Michaelmas.

You may by this method of laying the young wood, propagate almoſt any trees or ſhrubs you deſire: but it is chiefly intended for the hard wooded kinds of ever-greens, and others, which do not put out roots freely from older ſhoots or branches; but ſuch trees as ſhed their leaves, and even ever-greens whoſe wood is ſoft, it is beſt, for the generality, not to lay them till after Michaelmas, or in February or March; chooſing at theſe times the laſt ſummer's ſhoots.

Tranſplant Pines and Firs.

Some of your young pines and firs raiſed this ſeaſon from ſeed, ſhould, about the laſt week in the month,

be

be transplanted; but before that time they will be too tender to be removed.

In order to this, let some beds about three feet broad be prepared, and the young plants be pricked into these beds, about three inches asunder every way; remembering to refresh them with water as soon as transplanted.

It will be necessary to shade them from the mid-day sun till they have taken root, which may easily be done by fixing hoops across the bed, and throwing mats over the bed every sunny day from ten in the morning till about three or four in the afternoon.

By this method the plants will soon take root, so that those which were pricked out at this season, will have acquired strength sufficient by Michaelmas, to enable them to endure the winter's cold much better than if they had remained in the seed-bed.

Shade Seedling Trees.

You must remember to shade the beds of some of your seedling exotic plants from the sun in very hot weather, particularly those of the ever-green kind.

They must not however be shaded too close, or too long at a time, for that would draw the plants up weak, and make them too tender. It will be sufficient if they are shaded from about eleven in the morning till two or three in the afternoon.

Water Seedling Trees.

All seedling trees and shrubs must be watered in dry weather, particularly young cedars, cypress, pines, firs, junipers, bays, hollies, evergreen oaks, arbutus, and indeed all other kinds of ever-green seedling plants.

But be very careful not to water them too hastily, lest you wash away the earth from their roots, which are yet very small and tender. Two or three moderate waterings in a week will be sufficient, and the most proper time for it is the evening.

Water new Planted Trees.

Such trees as were planted late in the spring should be watered in dry weather, once every week during the whole month.

Remember also to keep some mulch upon the surface of the ground about your new planted trees; for this will not only save some trouble in the watering, by preserving the moisture longer in the earth, but also protect their roots from the drying winds and sun; and consequently enable them to shoot with more vigour.

When, therefore, you perceive the mulch laid some time since upon the roots of new planted trees to be much wasted, let fresh be added, particularly about the choicest plants, and such as were planted late in the season.

Weed the Seed-beds of Young Plants.

Remember to keep the seed-beds of young plants entirely free from weeds of every kind, for at this season of the year they rise as fast as in April or May. No labour therefore should be spared to destroy them before they grow large, especially in the beds among the seedling plants; for there they will inevitably do the greatest mischief.

The FRUIT-GARDEN.

Apple, Pear, Plum, and Cherry-Trees.

Your apple, pear, plum, and cherry-trees, whether planted against walls or espaliers, will now have made strong shoots, and therefore require regulating, provided it was not done in May.

Let therefore these trees be now cleared from all useless and unnecessary shoots; let them be taken off close.

But remember to leave, at moderate distances, in every part of the tree, some of the best grown and well-placed shoots; for in all probability some of these will be wanted to lay in and supply some place or other of the tree in the winter pruning. And whenever there appears an absolute want of wood, in any part of these trees, leave, if possible, some good shoots in these parts.

When all the useless shoots are taken away, let the remaining shoots be nailed, or otherwise fastened up close to the wall or espalier, and each shoot at its full length.

Apricot, Peach, and Nectarine-Trees.

If any of your apricot, peach, or nectarine-trees were not put in order last month, it must be done now, and the sooner the better. For where these trees are suffered to remain long in the wild confused manner they naturally grow into at this season, it will prove injurious to the trees themselves, and greatly retard the growth and ripening of the fruit.

Let therefore these wall-trees be gone over as soon as possible, clearing away all the ill-grown and ill-placed shoots: remember to take them off close to the place where they are produced.

At the same time be sure to leave in every part of these trees, a sufficient quantity of the best shoots for bearing next year; that is, leave all the regular and moderately growing shoots, provided they can be conveniently trained in, fastening them close to the wall in a neat manner.

Remember not to shorten any of the shoots for the reasons given last month, but lay them in, whether large or small, at full length; taking care to train them in such a manner, that their leaves may afford a moderate shade, in hot sunny days, to the fruit; for all kind of wall-fruit thrive best under a slight cover of leaves. At the same time the leaves will also prove a shelter to the fruit from the cold air of the night.

Thin Wall-Fruit.

If the fruit on any of your apricot, peach, or nectarine trees were not thinned last month, let it now be done as soon as possible; observing the same method in doing it, as mentioned last month.

Vines.

Let your vines planted against walls be now looked over and regulated, unless the work was done last month.

If this be not done at the beginning of the month, it will be impossible to procure, at a proper season, large and well ripened grapes. For where the vines are suffered to run into disorder, the bunches will be small and irregular, and the grapes small and ill tasted.

Let

Let ſuch of the vines therefore, which were not regulated in May, be now regulated with all expedition; clearing away all uſeleſs ſhoots, and nailing all that are uſeful cloſe to the wall in a neat and regular manner.

When this is done, let thoſe vines which were looked over and regulated in May, be now again looked over; clearing away all ſhoots in general that have been produced ſince laſt month. Be ſure to rub off thoſe ſmall ſhoots which riſe from the ſides of the ſame ſummer ſhoots.

Vineyards.

The vines planted in vineyards will now require a conſiderable ſhare of attendance, to prevent their running into confuſion; and in preventing this confuſion the whole ſucceſs depends.

Let therefore the bearing ſtocks be trained to the ſtakes with ſome degree of regularity; ſo that every ſhoot may equally enjoy the benefit of the ſun and free air. At the ſame time let all weak and ſtraggling ſhoots be diſplaced, together with thoſe which cannot be trained to the ſtakes in proper order.

It will be alſo very neceſſary to deſtroy the weeds whenever they grow in the vineyard; for this will be of the utmoſt advantage to the growth and timely ripening of the grapes.

New Planted Trees.

Let ſuch fruit-trees as were planted laſt autumn, winter, or ſpring, particularly ſtandard-trees, be now examined. See that they be well ſecured, ſo that they cannot be rocked about by the wind, which would diſturb their roots.

At the ſame time take care to keep the earth well cloſed about the ſtems of new planted trees, that neither the ſun or wind may have acceſs that way to dry the earth near the roots.

The apricot, peach, and nectarine trees which were headed down in the ſpring, ſhould alſo now be looked over. They will have made ſtrong ſhoots, which ſhould now be nailed to the wall, to ſecure them from the power of the wind.

Budding or Inoculating.

About the third or fourth week in this month, you may begin inoculating the early kinds of apricots, peaches, and nectarines.

But remember to perform the operation in cloudy weather, if poſſible; but if no ſuch weather happen, let it be done in the morning or evening.

Plum ſtocks raiſed from ſtones, are the moſt proper for budding the above fruit upon; the ſtocks ſhould be about two or three years old.

If the tree be intended for a dwarf, or for the wall, let the bud be inſerted in the ſtock about ſix inches above the ground; but if the tree be intended for a ſtandard, three or four feet above the earth will not be too much. But whatever height be allowed the ſtock, remember to make the inciſion for receiving the bud in a ſmooth part of the ſtock.

We have already explained the manner of performing this operation in the work of the nurſery for the preſent month, and therefore ſhall not repeat it here.

Plant Strawberries.

If new plantations of ſtrawberries are wanting, you may provide plants for that purpoſe about the middle or latter end of the month.

Let theſe plants be taken from ſuch ſtrawberry-beds as bear well, and produce large fruit. From theſe beds chooſe a parcel of the ſtrongeſt plants, and take them up carefully with their roots, which you are to trim a little, and cut off the ſtrings from the heads of the plants.

When this is done, let them be immediately planted into a nurſery-bed, prepared for them in a ſhady ſituation, about three or four inches aſunder, giving them a moderate watering to ſettle the earth about their roots.

In this nurſery-bed they are to remain till September or October, when they will have gathered ſufficient ſtrength, and be in excellent order to be removed into the bed where they are to remain; but they muſt then be planted a foot aſunder every way.

This method is not uſually practiſed, though much better than the common; becauſe the plants will be much ſtronger by September, than any that can then be procured from the old beds.

Water Old Strawberry-beds.

You muſt remember to water your ſtrawberry-beds in dry weather, every two or three days from the beginning till about the middle of the month; for about that time the principal crop of moſt kinds of ſtrawberries will be ſetting their fruit, and ſwelling to their reſpective ſizes; and while the fruit are growing, they ſhould be encouraged by keeping the earth in the beds always in a middling degree of moiſture: you will ſoon be convinced that you have not taken this trouble in vain by the ſize, as well as by the quantity and quality of the fruit.

Deſtroy Snails, &c.

Be very careful to look over your fruit-trees, particularly your apricot, peach, and nectarine trees, for ſnails every morning and evening, and eſpecially after ſhowers of rain; for at theſe times the ſnails leave their retreats, to feed upon the fruit.

The Pleasure or Flower-Garden.

Carnations.

You muſt now be very careful of your choice carnations; for towards the latter end of this month, they will begin to break their pods for flowering.

Art will be neceſſary to give them one of their principal beauties, that of opening regularly. Let therefore the inner cup or flower pod be cut open a little way in ſeveral places, in order to aſſiſt the opening and ſpreading of the petals, or flower-leaves.

This operation ſhould be performed juſt as the flower begins to break the pod. A ſmall pair of pointed ſciſſars will be very proper for this purpoſe. With theſe let the pod be cut a little way down, from each notch or indenting at the top. But be very careful not to cut the pod too deep at firſt; but rather open it a little at each place; and in a day or two after cut it down a little farther, if the former be not found ſufficient.

You muſt however remember in performing this operation, to leave ſo much of the bottom of the pod entire, as will anſwer the purpoſe of keeping all the petals, or flower-leaves regularly together.

If you omitted to place your carnations in pots upon the ſtage in May, let it be done now; but you muſt not

not cover the top of the ſtage till the flowers are opened; and then the cover muſt be conſtantly kept on, to defend them from the fierce rays of the ſun, and from heavy rains.

Remember to water them three times a week at leaſt; that is, you ſhould repeat the operation whenever you perceive the ſurface of the earth in the pots to appear dry; for it ſhould always be kept in a middling degree of moiſture.

It will be alſo neceſſary, as the flower-ſtalks of theſe plants riſe in height, to tye them up to the ſticks. They ſhould be tyed in ſeveral places, bringing the ſtalk to touch the ſtick: but do not tye it too ſtrait.

Tranſplant Carnation and Pink Seedlings.

About the middle of the month, your carnation and pinks raiſed this year from ſeed, will be fit to tranſplant from the ſeed-bed into the nurſery.

In order to this, let a bed or two of good earth, three feet and a half broad, be prepared, by breaking the clods well, and raking the ſurface even.

When the beds are thus prepared, take up your plants carefully, and ſet in each bed ſix rows of plants, by means of a line, ſix inches from each other in the row. As ſoon as they are planted, let a gentle watering be given them; and the operation be repeated once every two days at leaſt, in dry weather, till they have taken root.

In this bed they are to remain ten or twelve weeks, when they muſt be removed into another, and planted a foot aſunder every way.

Remember when they flower, which will be next year, to examine them very attentively, eſpecially the carnations, for there will certainly be found among the whole ſome new and very good flowers; and theſe are to be then increaſed by layers, according to the general method.

Method of laying Carnations, Pinks, and double Sweet-Williams.

About the middle of this month ſome of your carnations will be fit for laying, which is done in the following manner:

Provide ſome rich earth in a barrow or baſket, a ſharp penknife, and a ſufficient number of ſmall hooked pegs.

When theſe things are in readineſs, clear away all the weeds and other litter found about the plants; ſtir the ſurface of the earth a little, and lay thereon as much of the freſh earth as will raiſe the ſurface round the plant to a ſufficient height; ſo as readily to receive the ſhoots or layers.

This being done, pull off the leaves from the lower part of the ſhoot; letting thoſe which grow upon the head of it remain, after cutting off about two inches of their tops. Then fix upon a joint about the middle of the ſhoot, and placing the knife on the under ſide of it, ſlit the ſhoot from that joint, rather more than half way up towards the next above.

When you have proceeded thus far, make an opening in the earth, and lay the ſhoot immediately, ſecuring it there with one of the hooked ſticks. Remember to raiſe the ſhoot gently up, ſo as to make the head of it ſtand as upright as poſſible, and ſee that the ſlit be open. Then cover up the body with mold of the ſame mould, and in that manner proceed till they all are layed.

But remember, as ſoon as all the ſhoots belonging to one plant are layed, to give them a gentle watering, which will ſettle the earth regularly about all the layers. The waterings muſt be repeated in dry weather; but let them always be moderate, otherwiſe there will be great danger of diſturbing, or waſhing away the earth from the layers.

Theſe layers, in about ſix weeks time, will be finely rooted, and muſt then be taken off from the old roots, and planted, ſome of the beſt into ſmall pots, and the reſt into nurſery-beds, where they are to remain till October; at which time they may be taken up with balls of earth about their roots, and planted in the borders.

Method of Propagating Carnations and Pinks by Cuttings.

Beſides the above method of increaſing carnations and pinks, eſpecially the latter, there is another, which the gardeners call pipeing. It is performed in the following manner:

About the middle or latter end of this month, the plants will have made proper ſhoots for this operation. Let therefore the upper part of the ſhoots intended for this purpoſe be taken off; and if the cutting, or, as the gardeners call it, the pipeing, hath two points when taken off, it is ſufficient: ſome take them off with a knife, cutting them cloſe above a joint; but it is much better to take them off with the hand only; the method is this: Take the head of the ſhoot between the ends of the fingers and thumb of the right hand, holding the lower part of the ſhoot with the left; then pulling the head of the ſhoot gently, it will readily part and come out of its ſocket, about the third joint from the top.

Having by this means procured a ſufficient quantity of ſhoots, let their tops be trimmed pretty ſhort, and if the bottom of the cutting appear ragged, let that be cut even; and having prepared a bed, or pots, of light rich earth, broken very fine, and the ſurface made very ſmooth, take the cuttings, one by one, between your fingers and thumb, and thruſt them gently near half way into the earth, putting them about an inch, or an inch and half, diſtant from one another.

Remember, in planting, to make no hole to receive the cutting, but only thruſt the end gently into the earth; for it will make way for itſelf; and, as ſoon as a quantity is planted, to give them a gentle watering.

It will be neceſſary to ſhade them from the ſun, from nine in the morning till about five or ſix in the evening. And if theſe cuttings can be conveniently covered with glaſſes, it will prove of the greateſt advantage; they will then take root freely, and be fit for tranſplanting a fortnight or three weeks ſooner than if they were fully expoſed to the open air.

But however that be, remember to refreſh them frequently with water, ſo as to keep the earth about them a little moiſt.

Tranſplant Chryſanthemums, French and African Marygolds, &c.

You may now, when the weather is ſhowery, tranſplant chryſanthemums, French and African marygolds, perſicarias, tree and purple amaranthuſes, ſcabiouſes, egg-plants, ſtramonium, palma Chriſti, love-apple, tobacco

bacco plants, marvel of Peru, balſams, capſicums, China aſters, Indian pinks, ten-week ſtocks, the large convolvulus, and ſeveral others.

In order to this, let them be carefully taken up with balls, or, at leaſt, with as much earth as will readily hang about their roots; and in that manner let them be planted in the beds, borders, or other parts of the garden. Remember, when you plant them, to cloſe the earth well about their roots and ſtems, and immediately to give every plant a little water, repeating it occaſionally till they have all fairly taken root.

As they advance in height, let the larger kinds be properly ſupported with ſticks; for great part of the beauty of theſe flowers conſiſts in their having fair and upright ſtems; they muſt therefore be properly trained and ſupported.

Tender Annuals.

You muſt often refreſh your tender annuals, ſuch as cockſcombs, tricolars, globes, double balſams, double ſtramoniums, &c. with water. They will require it three times a week, at leaſt; but let it always be moderate.

They muſt alſo be allowed a large quantity of freſh air every day, which muſt be given them by tilting up the lights with props, or ſliding them a little way open.

Thoſe balſams, cockſcombs, tricolars, &c. which are grown to any tolerable ſize, and are pretty ſtrong, may, about the laſt week of this month, be brought into the open air; but thoſe which are ſmall and weakly, ſhould remain under the glaſſes a week or two longer.

Propagate Fibrous-rooted Plants.

This is a proper ſeaſon for propagating perennial fibrous-rooted plants, which is done by ſetting the flower ſtalks.

The double ſweet-williams, double ſcarlet lychnis, lychnideas, and ſeveral other ſorts of perennial plants of that tribe, may be increaſed by this method, which is performed in the following manner:

Let ſome of the ſtouteſt flower ſtems be cut off cloſe to the head of the plant, and theſe cuttings divided into lengths, each containing two or three joints.

Your cuttings being thus prepared, plant them about four inches aſunder in a ſhady border; remember to put two joints of the cuttings into the ground, and to give them immediately a little water.

If you cover theſe cuttings with hand-glaſſes, it will greatly aſſiſt them in taking root.

Tranſplant Autumnal Flowering Bulbs.

All thoſe bulbous and tuberous-rooted plants which grow in autumn, may now be taken up and tranſplanted; particularly colchicums, autumnal crocuſſes, hyacinths, narciſſuſſes, and other autumnal flowering plants of this kind, whoſe leaves are now decayed.

Remember, when you take up the roots, to remove all the off-ſets. After which, they may be either planted again immediately, or kept out of the ground till the firſt or ſecond week in Auguſt. But if they are not planted at that ſeaſon, they will not blow in autumn with any degree of ſtrength.

The leaves of your calcamens will be alſo now decayed; let the roots therefore be taken up, parted, and planted again in freſh mould. They generally flower in February or March, according to their ſituation.

Tranſplant Seedling Plants.

Your wall-flowers, ſtock july-flowers, ſweet-williams, and columbines, ſown in March or April, ſhould be now tranſplanted into nurſery beds about ſix inches aſunder, and have a good watering given them, to ſettle the earth about their roots.

In this bed the plants are to remain till about Michaelmas, and then removed into the borders, &c. where they are intended to remain. Their flowers will make an elegant appearance next ſummer.

Hollyhocks, tree-primroſe, fox-gloves, pyramidal campanulas, Canterbury-bells, Greek valerian, ſingle roſe campion, rockets, ſcarlet lychnis, and other perennial plants ſown in the ſpring, ſhould be now tranſplanted into nurſery beds about ſix inches apart.

In theſe beds they are to remain till they become ſtrong and handſome plants, which will be about September or October, when they are to be taken up and planted out, where they are to remain to flower.

And if they are judiciouſly placed in different parts of the garden, they will make a very elegant appearance next ſummer, when they will all flower.

Take up the Roots of Tulips, Jonquils, Crown Imperials, &c.

Some time this month the leaves of your tulips, jonquils, &c. will begin to decay; and when this happens, it is a proper time to take the roots out of the ground.

Remember to do this in dry weather, and to ſpread them thinly upon mats, laid in the ſhade, to dry, as ſoon as they are taken out of the ground.

As ſoon as they are thoroughly dry, and ſomewhat hardened, let them be very well cleaned, and all the off-ſets ſeparated from the large roots. When this is done, let them be put up, each ſort by itſelf, in bags or boxes, till September, October, or November, when they are to be all re-planted.

By this method of taking up the choiceſt bulbous roots of any kind, as ſoon as their leaves decay, they are prevented from exhauſting themſelves too much, which many ſorts would do, were they permitted to remain in the earth; becauſe they would ſoon put out new fibres, and conſequently ſet all the roots a growing at an unſeaſonable time of the year.

Beſides, it is neceſſary to take up all kinds of bulbous roots once every year, in order to ſeparate the ſmall off-ſets from each of the principal; particularly tulips, jonquils, hyacinths, and others of the choicer kinds of bulbs; and there is no time ſo proper to take them up, as when the leaves and flower ſtalks of the different kinds begin to decay; for then the roots are in a ſtate of reſt; but if permitted to remain three weeks or a month after that period, they will put out freſh fibres, and the root would begin to form the bud for the next year's bloom; and if they were then to be taken up, would, in ſome meaſure, check the next year's flower; that is, it would not blow ſo large as it would, had it been taken up immediately at the decay of the leaves.

Guernſey Lilly Roots.

The leaves of the Guernſey and Belladona lilly roots will be now decayed, and conſequently it is a proper ſeaſon to take up the roots.

As ſoon as they are taken up, and the off-ſets taken from them, they ſhould be planted ſingly in beds of earth

earth newly dug, or in pots filled with new compoſt; for this will greatly encourage them to ſhoot, and conſequently increaſe the largeneſs and beauty of their flowers.

Ranunculus and Anemony Roots.

As the leaves of the ranunculus and anemony roots will now begin to wither, they ſhould be taken up.

But a conſiderable deal of care is neceſſary in taking theſe roots out of the ground; and it ſhould always be done in a dry day, when the ground is pretty dry.

When the roots are taken up, they ſhould be dried in the ſhade, and preſerved in a dry place till the ſeaſon for planting them arrives.

Hyacinth Roots.

As ſoon as the hyacinths are paſt flowering, and their leaves begin to decay, let the roots be taken up, at leaſt all thoſe of the fine double kind.

As ſoon as theſe roots are taken up, they ſhould be immediately committed to the ground again, though in a different manner: they muſt be laid ſideways into a bed of light earth, covering the roots, but leaving the ſtalks and leaves out of the ground.

In this bed the roots are to lie for ſome time, in order to ſwell and harden, which they will do ſufficiently by the time the ſtalks and leaves are perfectly decayed.

The method of preparing the bed, and laying the roots, is this:

Let a bed of light earth be dug one ſpade deep. When this is done, rake the earth up from each ſide of the bed towards the middle, ſo as to form an eaſy rounding kind of ridge from one end to the other of the bed.

In this ridge of earth the roots are to be laid; obſerving that they are not now to be placed with their bottoms downward; but each root muſt be laid fairly on its ſide, with the ſtalks and leaves hanging out.

In the above poſition, let them be laid in two or three rows on each ſide of the ridge; placing the roots about two inches aſunder in the rows, and covering the roots equally with earth.

When the roots have laid in this bed about twenty days, they will be fully ſwelled, and thoroughly ripened; when they muſt be taken out of the ground in a dry day, well cleaned, and then ſpread upon a mat in a dry ſhady place. In about ten or twelve days after this, they muſt be put up into boxes till September or October.

Auricula Plants.

If you omitted laſt month to place any of your auricula plants growing in pots in a ſhady ſituation, let it be done now.

But remember to water the pots frequently in dry weather, and to keep both the pots and the place where they ſtand, free from weeds.

Support and Trim Flowering Plants.

You ſhould be very careful to ſee that every one of your tall growing plants be properly ſupported with ſticks. For nothing gives plants a better appearance than their ſtanding firmly in their places, and their being trained neatly with ſtraight and upright ſtems.

At the ſame time viſit your plants, trimming ſuch as ſtand in need of it.

All ſtraggling, broken, and decayed ſhoots, together with all ragged or decayed leaves, ſhould be taken away.

Cut down the flower-ſtems of ſuch perennial plants as are paſt flowering. But, in doing this, remember to let the ſtems be cut off cloſe to the head of the plant; and, at the ſame time, to clear the plant from all dead leaves. Unleſs you intend to ſave the ſeeds; for then it will be neceſſary to leave, for that purpoſe, ſome of the principal flower-ſtems, cutting off all ſuch as are weak and ſtraggling.

Management of Evergreens and Flowering Shrubs.

Examine your clumps or quarters of evergreens and flowering ſhrubs; and wherever you find any of them to have made any diſorderly ſhoots, let them be reduced to order, either by ſhortening them, or cutting them off cloſe.

At the ſame time, remember to keep the whole exceeding neat, and free from weeds.

Cut Box Edgings.

About the middle of this month is a proper ſeaſon for cutting box edgings, provided the weather be moiſt; for it ſhould never be done in dry weather.

Theſe edgings ſhould never be ſuffered to grow above three inches high, nor more than two broad. Remember to cut them very neat and even.

Clear the Borders from Weeds.

Be very careful to keep your borders free from weeds, and all kinds of litter. For if you permit the weeds to remain on any of the borders, eſpecially thoſe near walks, they will give the whole a very unſightly appearance. If the hoe be uſed for this purpoſe, let it be done in a dry day; and after the weeds are cut up clean below the ſurface of the ground, let the whole border be neatly raked.

Mow Graſs-Walks and Lawns.

As ſoon as ever you perceive the graſs to be grown of an unſightly length, let the walks and lawns be mown. They will, in general, require this labour once a week, which will keep them in tolerable good order.

At the ſame time, the edges of graſs-walks and lawns ſhould be kept cut very cloſe; for this will add greatly to their neatneſs and beauty.

Gravel Walks.

You ſhould alſo remember to keep your gravel-walks extremely neat and clean at this ſeaſon.

The principal walks ſhould be rolled at leaſt twice a week, with an iron or ſtone roller. The former is much the beſt, as it will be drawn with more eaſe, and render the ſurface of the gravel ſmoother than any other.

JULY.

Work to be done in the KITCHEN-GARDEN.

Cucumbers.

YOUR cucumber plants will now demand attention, particularly thoſe which are planted under hand or bell-glaſſes.

They will now be in full bearing, and therefore muſt be well ſupplied with water in dry weather. They ſhould have a moderate watering once every other day.

If this be complied with, and the beds kept entirely free from weeds, the plants will continue to bear handſome and well-taſted fruit till the middle of September.

Cucumbers for Pickling.

The cucumber plants ſown in the natural ground for picklers will alſo require ſome care.

You muſt remember to lay out their vines in regular order, as they begin to advance: and if the ground between the holes of theſe plants was not dug laſt month, let it be done now; and as you proceed in the digging, let the vines be laid out in a neat manner, at regular diſtances. At the ſame time, let ſome earth be laid between the plants, preſſing it down gently, in order to part, and make them ſpread different ways, according as you would have them run. Remember alſo to draw the earth up round each hole, in order to form a baſon for holding the water given them in dry weather; for they will require frequent waterings.

Melons.

The melon plants, whoſe fruit are now beginning to ripen, will require particular regard.

Very little water muſt now be given theſe plants, for too much moiſture would ſpoil the fine taſte of the melons. They muſt, however, in very dry and hot weather, be moderately watered now and then. But regard muſt always be had to the nature of the earth, and its depth upon the beds. Where there is a conſiderable depth of good loam, we mean twelve or fourteen inches, the plants ſhould not, when their fruit is full grown, be allowed any more water; for good loam, where it is of a tolerable depth, will retain a moderate and proper degree of moiſture for a long time.

But ſuch melons which grow in common light earth, and where there is, at the ſame time, but a moderate depth of it upon the beds, the plants will, in very hot weather, ſtill require water; but then it muſt be done with moderation, and not repeated above once a week.

Protect Melons from heavy Rains.

If the weather ſhould be very wet at this ſeaſon, which ſometimes happens, your melon plants muſt be occaſionally protected.

This may be done without any difficulty, where the plants grow under frames; but it will be different with regard to thoſe planted out under hand or bell-glaſſes. All poſſible means muſt, however, be uſed to ſhelter them, when the weather happens to be uncommonly wet; for theſe plants will be now full of fruit.

In order to this, let the fruit, at leaſt as many of them as are ſwelled, be put under their own bell-glaſſes; or, where there are any ſpare glaſſes, let them be placed over the fruit.

Another method is to place hoops over the ridges or beds, about ſixteen or eighteen inches from one another; and when it rains very hard, let ſome large and thick mats be drawn over the hoops; or, which will be ſtill better, pieces of painted canvas.

But whatever covering be uſed, remember that it is not to remain any longer than juſt to defend the plants from heavy rains; for a free circulation of air will be now abſolutely neceſſary.

Savoys and Cabbages.

Let a ſpot of good ground, in an open ſituation, be now prepared for a principal crop of ſavoys, and winter cabbages.

As ſoon as the ground is dug and raked, let the plants be ſet at eighteen or twenty inches aſunder every way.

Broccoli.

You muſt now remove your broccoli plants intended for a full crop into the place where they are to remain.

Let a piece of the beſt ground be choſen for this purpoſe, and the plants ſet in rows two feet aſunder, and about twenty inches apart in the rows. Give them a little water as ſoon as they are planted; and if the weather ſhould prove dry, let the waterings be repeated once every two or three days, till the plants have all taken root.

But theſe plants ſhould, if poſſible, be planted out in a ſhowery time; which will prove an advantage to the plants, and alſo ſave conſiderable trouble in the watering.

You ſhould now ſow a little broccoli-ſeed for the laſt time this ſeaſon: it ſhould be done before the end of the ſecond week in the month.

In order to this, let a rich ſpot of ground, where the ſun has not too much power, be choſen; and after the ſeed is ſown, let the bed be often ſprinkled with water, in dry weather; for this will both aſſiſt the plants in their ſpringing and growth.

About the latter end of Auguſt, the plants ſown now, will be ready to plant out for good, and produce heads in April, or the beginning of May.

Cauliflowers.

You muſt now plant out the cauliflower plants ſown in May for the autumnal crop, where they are to remain.

Remember to chuſe a ſhowery time for this work; and to plant them in rows two feet aſunder every way. Let them be watered as ſoon as planted, and the watering

ing frequently repeated, in dry weather, till they have taken root.

Kidney-Beans.

Kidney-beans, either of the dwarf or running kind, may now be planted for a late crop.

But remember to let the ſeeds be in the ground before the end of the firſt week in the month; otherwiſe they will not ſucceed. You ſhould alſo remember to plant them where they may be ſheltered from the nipping morning froſts, which too often happen in September; for this crop will continue bearing, if the weather continues any thing mild, till October.

The following caution likewiſe ſhould be obſerved, in planting theſe beans.

If the weather, at the time of planting, be very hot, and the ground very dry, it will be proper to ſoak the beans in rain, river, or pond water, about ſix or ſeven hours before they are ſet. But remember to plant them as ſoon as ever they are taken out of the water. The dril's alſo ſhould be watered before the beans are dropped into them.

This ſoaking of the beans is only neceſſary when the weather is very hot, and the ground very dry; for, at other times, it will be better to let the drills only be watered, and the beans immediately planted.

Sow Onions.

The laſt week in this month, but not before, you may ſow onions to ſtand the winter.

Let therefore a rich ſpot of ground, in a ſheltered ſituation, be dug, and divided into beds three feet and a half, or four feet broad. Sow the ſeed immediately, tolerably thick, and rake it in. The plants will ſoon come up, and gather ſtrength ſufficient by Michaelmas, to enable them to reſiſt the cold of the winter. They will be fit for ſallads, and other purpoſes, in March and April.

Remember when the plants are come up to let them be weeded in time; for, otherwiſe, the weeds, which will riſe with the onions, will ſoon get the ſtart of them, and deſtroy the whole crop.

Sow Turneps.

Turneps for autumn and winter uſe may be ſown any time this month. But, if poſſible, let it be ſown in a ſhowery time, for a little rain will now be of the utmoſt advantage to the ſeed.

Remember not to ſow the ſeeds too thick, but as regularly as poſſible; the ſame care will alſo be neceſſary in raking in the ſeed; let it be done lightly, and with an even hand.

Thoſe turneps which were ſown in June muſt now be hoed; but let this be done in dry weather; at the ſame time cut down all the weeds, and thin out the plants to ſeven or eight inches diſtance.

Sow Winter Spinnage.

The beſt ſorts of ſpinnage for ſowing at this ſeaſon, are the prickly-ſeeded kinds; theſe being more hardy than the other ſorts, and conſequently better able to endure the cold of the winter.

Near the latter end of the month, let a clean well ſituated ſpot be nearly dug; and as ſoon as the ground is ready, let the ſeed be ſown. Remember not to ſow it too thick, but as equal as poſſible; and to rake it in with an even hand. Some tread the ground as ſoon as the ſeed is ſown, and then rake the ſurface ſmooth and even. Either method will ſucceed, and perhaps almoſt equally.

Sow Turnep-rooted Raddiſhes.

There are two ſorts of the turnep-rooted raddiſh, the one black, and the other white, and are generally called the black and white Spaniſh raddiſh.

Between the tenth and twenty-fourth of this month, will be a very proper time for ſowing the ſeeds of either. But remember to chuſe an open ſpot of ground for this purpoſe.

Soon after the plants are come up, they ſhould be hoed out to five inches diſtance, that their roots may have room to ſwell. They will be ready to draw for the table about Michaelmas, and will continue good, eſpecially the black ſort, till Chriſtmas, unleſs the froſt be very ſevere; in which caſe they ſhould be drawn out of the earth, and preſerved in ſand.

Sow Common Raddiſhes.

If theſe plants are wanted, as in ſome families they are, ſome of the ſeed may be ſown the laſt week in this month, but not before. The plants will ſoon come up, and be ready to draw for the table by the firſt or ſecond week in September.

Sow Cole-worts.

This is the very beſt ſeaſon in the whole year for ſowing cole-worts. They are very uſeful in families, as they will ſupply the table in the ſpring, when the ſavoys and other greens of that kind are over.

But remember not to ſow this ſeed before the twenty-fourth of the month, when an open ſpot of rich ground ſhould be prepared for its reception, and divided into beds four feet wide. In thoſe beds let the ſeed be ſown moderately thick, and raked in lightly with an even hand.

In about a week after ſowing, the plants will come up, and by the middle of September be ſtrong enough to be tranſplanted; when they are to be ſet in rows a foot aſunder, and eight inches apart in the rows.

Sow Endive.

You may now ſow ſome endive for the principal winter crop. But it muſt be ſown the firſt week in the month, or it will not ſucceed.

Let the ſeed be ſown tolerably thin, in a rich open ſpot of ground, and lightly raked in with an even hand.

Remember to water the bed frequently in dry weather; for this will be of great ſervice in bringing up the plants ſoon, and alſo in cauſing them to riſe regularly.

Sow Small Salleting.

Creſſes, muſtard, raddiſh, and other ſmall ſallad herbs, may now be ſown if required.

But remember to ſow the ſeeds, each ſort ſeparate, in a ſhady border, in ſhallow drills. If the weather be dry, there will be a neceſſity for daily watering the bed, for the plants will not riſe regularly.

If a conſtant ſupply of theſe ſmall ſalleting herbs be wanting, a little of the ſeed ſhould be ſown once every week.

Sow Carrots.

A little carrot-ſeed may be ſown the firſt or ſecond week in the month, in order to raiſe ſome young carrots for the table in autumn; about Michaelmas they will be fit to draw, and continue very fine all October and November.

Sow Lettuce.

The Coſs, Sileſia, or Dutch lettuce are moſt proper to be ſown at this ſeaſon.

About the firſt or ſecond week in the month, let a ſpot of rich ground be dug, and the ſeed ſown on it immediately. The plants will be fit for the table in the beginning of September.

And if a little more ſeed be ſown on another ſpot of ground the laſt week in the month, a regular ſupply of lettuce will be continued till November, if the weather be favourable.

Tranſplant Endive.

A parcel of the ſtrongeſt endive plants muſt be now removed to ſupply the table in autumn.

But you muſt remember that endive requires a good ſoil, well dug, and the ſurface ſufficiently raked.

As ſoon as a ſpot of ground is thus prepared, let your plants be ſet in it, a foot diſtant from each other every way. They muſt be watered as ſoon as planted; and the waterings repeated every other day in dry weather, till the plants have taken root.

Tranſplant Celery.

You muſt now prepare your trenches for planting out a good crop of celery.

In order to this let an open ſpot of rich ground be choſen, and well cleared from weeds. When this is done, mark out the trenches about a foot broad, allowing an interval of three feet and a half between the trenches. Let each trench be dug about a ſpade deep, and the earth that comes out laid neatly in the interval between the trenches, remembering to ſpread it as even as poſſible.

When this is done, let ſome good rotten dung be laid at the bottom of the trench, and dug in.

This being performed, chooſe a ſufficient number of the ſtrongeſt of your plants, trim the ends of their roots, and cut off about two inches of the tops of their leaves, and then plant them in the trenches.

Remember that one row only muſt be planted in each trench, and that this row be directly in the middle of it. Four or five inches will be a ſufficient diſtance between plant and plant; but ſome water muſt be given them immediately, and the waterings repeated occaſionally in dry weather, till the plants have taken root.

Tranſplant Lettuces.

The Coſs, Sileſia, common cabbage, and brown Dutch lettuces, ſown laſt month, ſhould now be tranſplanted.

In order to this let a ſpot of the richeſt ground be choſen, well dunged, and the ſurface raked very even.

When the ground is ready, put in the plants by a line, at the diſtance of twelve inches from one another

Give them a little water as ſoon as they are planted, and repeat the operation occaſionally, till they have all taken root.

Tranſplant Leeks.

You ſhould make choice of a good piece of ground for tranſplanting your leeks, as that will prove of the utmoſt advantage to the plants, eſpecially if a little rotten dung be ſpread on the ſurface and dug in.

When the ground is properly prepared, let it be divided into beds four feet broad. Then take up your leeks, chooſing the ſtrongeſt plants, and trim their roots and tops of their leaves. When this is done, let them be planted in rows, ſix inches apart every way.

Artichokes.

Your artichoke plants, which will now ſoon come into uſe, muſt be ordered in the following manner:

If you deſire to have large artichokes, you muſt, in order to encourage the main head, cut off all the ſuckers or ſmall heads which are produced from the ſides of the ſtems; and theſe in ſome families are dreſſed for the table.

You muſt alſo remember, that as ſoon as the principal head or artichoke is cut, let the ſtem be immediately broken down cloſe to the ground. This practice is indeed too often diſregarded; but this is utterly wrong; for the ſtems, if permitted to remain, would greatly impoveriſh the roots, and injure them much more than is generally imagined.

Plant Sage, Hyſſop, &c.

You may ſtill plant the ſlips of ſage, hyſſop, winter ſavory, and other herbs of that kind; for they will yet ſucceed.

The ſlips muſt be about ſix or ſeven inches long, planted in a ſhady border, and often refreſhed with water in dry weather.

Remember to chuſe ſuch ſlips as have ſtrength, and to put them two thirds of their length, at leaſt, into the earth.

Pull Onions.

About the latter end of this month, examine your forwardeſt crops of onions; and when their leaves begin to wither, it is a proper time to take the roots out of the ground.

It is not indeed very common that theſe roots are fit to be taken up this month; but when they are, let them be managed in the following manner:

Take them up in dry weather; and as you take them out of the earth, pull off their leaves, four or five inches of the ſtalk only being to be left to each onion. As ſoon as they are taken up, let them be ſpread to harden upon a clean, dry, ſpot of ground; and let them lay there twelve or fourteen days, remembering to turn them once every two or three days at leaſt, that they may dry and harden regularly.

When theſe have laid their proper time, they muſt be gathered up in a dry day, well cleared from earth and all looſe outer ſkins, and carried into the houſe; where they muſt be ſpread thin upon the floor of a dry airy room.

Remember to keep the windows of the room conſtantly open in dry weather, for about a week or ten days after the onions are houſed; but after that time no more air ſhould be admitted through the windows; nothing then being wanting but to turn them now and then, picking out all the decayed roots.

Pull

Pull Garlick and Shallots.

When the leaves of your garlick and ſhallots begin to wither, it is time to take the roots out of the ground. This will happen to the moſt forward plants ſome time this month, when they ſhould be taken up, and dried in the ſhade, nearly in the ſame manner as above directed for onions.

Gather Seeds.

As your ſeeds ripen, let them be gathered; but remember to do it in very dry weather.

As ſoon as the pods, or ſeed-veſſels are cut from the ſtalk, let them be ſpread immediately in a dry place, where a free current of air may be admitted to them. In this ſituation let them lie a fortnight or three weeks; when they may be beaten out of their pods, and preſerved in bogs or baxes for uſe.

Gather Herbs for Drying.

Baum, mint, hyſſop, winter ſavory, thyme, &c. ſhould be gathered, in order to be dried for winter uſe, ſome time this month.

But remember to let this be done when the plants are in flower; for then they are in their higheſt perfection. Remember alſo to cut them in dry weather, and to ſpread or hang them up in ſmall bundles, in a dry airy place, ſhaded from the ſun. In this ſituation let them remain and dry gently; for they muſt never be dried in the ſun.

Gather Herbs to Diſtil.

Many of the herbs proper for diſtillation will be now in flower, and conſequently proper to be cut for diſtillation. It will perhaps be unneceſſary to mention, that they ſhould be cut in a dry day; unleſs they are intended to be diſtilled by what is called a cold ſtill, when they ſhould be gathered in the morning with the dew about them.

Gather Chamomile Flowers.

About the latter end of this month, ſome of your chamomile flowers, together with thoſe of marigold and lavender, will be fit to be gathered.

But remember to do it in a dry day, and to ſpread them out thinly to dry in a ſhady place. When they are ſufficiently dry, put them up in paper bags for uſe.

Clear the Ground from Stalks, Weed, &c.

As many of your plants will now have done bearing, let the ground be cleared from their leaves, weeds, or any other kind of rubbiſh.

Pull up alſo the ſtalks and haulm of cauliflowers, beans, peas, &c. as are paſt bearing; together with other plants that are paſt ſervice; and clear them entirely off the ground.

When this is done the ground will have a neat apearance, and be in a proper condition to be dug, for receiving an autumn or winter's crop.

Nor is the elegance of the appearance all the advantage that will flow from this trouble; the ground will be in much better condition to receive the intended crops, than if the ſtalks, haulm, weeds, and other rubbiſh, had been ſuffered to continue; for they would have exhauſted a very conſiderable part of its ſubſtance.

The NURSERY.

Bud Apricots, Peaches, and Nectarines.

This is the principal ſeaſon for budding apricots, peaches, and nectarines; but remember to do it upon plum-ſtocks, which are the beſt adapted to theſe kinds of fruit. Theſe ſtocks ſhould be raiſed by ſowing the ſtones of plums; and they will be fit for budding in the third year of their growth.

With regard to the manner of performing the operation of budding, we have fully deſcribed it in the work of the nurſery of the foregoing month.

Bud Plums, Pears, Cherries, &c.

Plums, pears, cherries, &c. may alſo now be budded on their proper ſtocks. Plums, for inſtance, ſucceed beſt when budded on plum-ſtocks, raiſed by ſowing the ſtones; pears when budded upon quince or pear-ſtocks, raiſed by ſowing the kernels; and cherries when budded on cherry-ſtocks, raiſed from ſowing the ſtones.

In performing this operation, regard muſt be had to the nature of the intended tree. If it be deſigned for a wall or eſpalier, the budding ſhould be performed in a ſmooth part of the ſtock, about five or ſix inches above the ground; becauſe the tree will then readily furniſh the wall or eſpalier with bearing wood from the very bottom.

But if it be intended for a ſtandard, the budding ſhould be performed conſiderably higher, three, four, or even ſix feet from the ground. You muſt alſo remember to chooſe ſtocks that are grown to a proper ſize; otherwiſe they will not have ſubſtance ſufficient for receiving the buds at a ſufficient height from the ground.

Bud Jaſmines.

The budding of jaſmines is the moſt certain method of raiſing the more curious kinds; and this is the proper ſeaſon for performing the operation.

The common white jaſmine is the proper ſtock to bud the more curious kinds upon; and it ſhould be done the firſt or ſecond week in the month.

Examine new Grafted and new Budded Trees.

Look over all your new grafted trees, and diſplace all ſuch ſhoots as are at any time produced from the ſtocks below the graft, or bud; for theſe would rob the latter of their nouriſhment.

At the ſame time obſerve, where any of the grafts or buds have made vigorous ſhoots, to let every one of theſe ſhoots be ſupported with a firm ſtake.

Tranſplant Seedling Firs and Pines.

Whenever you find your young firs or pines ſtand too cloſe in their ſeed-beds, let them be tranſplanted now. For though they will now require a little more care than when tranſplanted next ſpring; yet they will ſucceed very well, provided they are properly watered and ſhaded from the ſun.

Let therefore beds be prepared, about three feet broad, the ground well broken, and the ſurface raked very even. Into theſe beds let the plants where they ſtand too thick in their ſeed-beds be tranſplanted, and watered immediately.

Remember

Remember to shade the plants every day from the sun till they have taken root; for otherwise they will be burnt up and destroyed. Let them also be supplied with water till they have taken root. The waterings should be moderate, and often repeated in dry weather.

If this method be observed, they will soon take root, and by Michaelmas have gained sufficient strength to endure the winter's cold. Indeed they generally do better than those which are suffered to remain in the seed-bed till March.

Water the Seed-beds of young Plants.

You must still continue to water the seed-beds of all young shrubs once in two or three days at least, during the dry weather.

This will prove of the utmost advantage to the young plants, provided the watering be always moderate; for if the water be poured on the beds too hastily, or given in too great a quantity at one time, it will greatly injure, if not totally destroy the plants.

Destroy Weeds.

As soon as ever you perceive any weeds in the seed-beds of your young plants, let them be destroyed; for nothing is so destructive to young seedling plants as weeds. These will do the young plants more injury in two or three weeks, than they will be able to recover in a twelvemonth.

But it is not enough that the beds alone be kept free from weeds; every part of the nursery must be the same; for this will be at once an advantage to the young plants, and give the whole a pleasing appearance.

When weeds appear between the rows of transplanted trees, they may be expeditiously destroyed by the application of a good sharp hoe in dry days.

Above all, be very careful that none of the weeds in any part of the nursery perfect their seeds; for whenever this is permitted, the seeds will fall upon the ground, and lay a foundation for a seven year's crop at least. Many of them also, by their particular form and appurtenances, will be wafted to a great distance from the mother plant, and fill the nursery with disagreeable inhabitants.

The FRUIT-GARDEN.

Budding.

This is a proper season for inoculating or budding fruit-trees.

You must remember to bud each sort upon its proper stock. Thus apricots, peaches, and nectarines, flourish best upon plum-stock; and generally make the strongest and most lasting trees when budded upon stocks raised from plum-stones.

Pears should be budded upon quince or pear-stocks, raised from the seeds of the respective trees.

Cherries are generally budded upon cherry-stocks, raised from the stones.

If any of your cherries, pears, or plums, grafted in the spring, have miscarried, they may now be budded with the same kind of fruit; for the trees equally succeed either by grafting or budding.

You should remember to perform this operation in cloudy weather; at least early in the morning, or in the evening after four o'clock; for the great power of the mid-day sun is apt to dry the cuttings so much, that the buds will not easily part from the wood.

When the trees are intended for the wall or espalier, the budding must be performed above four or five inches above the ground; but if they are designed for standards, four, five, or six feet will not be too much.

As we have already in the work of the nursery for June, described the method of performing this operation, it will be unnecessary to repeat it here; but it may not be amiss to add, that budding may also be performed upon trees that bear fruit.

If therefore you have either wall or espalier trees that produce fruit of a different kind than what you desire, you may bud them with the sort more agreeable; but remember to perform the operation on shoots of the same summer's growth.

You may even put several buds into one and the same tree, by which means the wall or espalier will be soon covered with the desired kinds, and the trees will, in two or three years after budding, begin to bear fruit.

Wall-Trees.

If any of your wall trees have not yet received their summer pruning and nailing, let it now be done as soon as possible, otherwise the fruit upon those trees will be both small and ill tasted, in comparison of what they would have been, had not this work been neglected.

Nor is this all, the trees themselves will likewise suffer; particularly the apricots, peaches, nectarines, and others, which produce the greater part of their fruit on wood of one year old.

If therefore any trees remain unpruned, let it be done the first week in the month, remembering to clear away all the luxuriant wood, and to displace all foreright or otherwise ill-placed shoots. At the same time leaving, and nailing close to the wall as many of the well-placed moderate growing shoots as can be conveniently laid in; especially of the apricot, peach, and nectarine trees. Remember not to shorten any of the shoots at this season; but let them all be laid in at full length.

With regard to those trees which were dressed and nailed during the two preceding months, let them now be again looked over, to see if all the shoots laid in last month keep firm in their places; and whatever seems amiss let it be rectified; at the same time observing to displace all the straggling shoots produced since the last pruning.

Vines.

You must now look over your vines once more, in order to clear them from such shoots as have been produced since last month. By pursuing this method, of rubbing off all the shoots as soon as they appear, your bunches of grapes will be large and well grown; every bunch will ripen regularly, and three weeks sooner at least, than where the vines were neglected, and permitted to be overrun with useless shoots.

Fig Trees.

This is a proper season for beginning to nail your fig-trees to the wall or espalier. Remember not to top or shorten any of the shoots, but to lay in as many of them as you conveniently can, in a strait and regular manner.

Destroy

Deſtroy Snails.

You muſt continue your aſſiduity with regard to deſtroying ſnails; for they will otherwiſe greatly damage your choiceſt wall fruits. Let the trees therefore be often looked over, early in the morning, and at the cloſe of the evening, eſpecially after ſhowers of rain.

Deſtroy Waſps, Hornets, &c.

Waſps, hornets, and other inſects of that kind will now devour many of your choiceſt fruits, if not careſully prevented. Let therefore a ſufficient number of phials filled with ſugar water, be hung upon the branches of the trees, before they begin to attack the fruit.

By this means the greater part of your choiceſt fruits will be preſerved; for the ſmell of the liquor will intice theſe inſects into the phials, where they will be drowned. But it will be neceſſary to look over your phials often, in order to empty the inſects they may contain, and to repleniſh the phials with a freſh quantity of the above ſweetened water.

The PLEASURE or FLOWER-GARDEN.

Management of Choice Carnations.

Your choice carnations will ſtill require a conſiderable degree of attention. Their flower pods, as they begin to break, muſt be aſſiſted by opening the pods deeper according to the manner directed in the preceding month; this is very neceſſary to promote their regular ſpreading, in which one of the principal beauties of choice carnations conſiſts.

Remember to refreſh the pots duly with water; in very hot weather they will require a little once every other day. Remember alſo to protect them, when in bloom, from wet and the mid-day ſun.

The beſt method is to have the top of the ſtage covered with a light covering, ſupported at a convenient height, that it may neither hide the flowers, nor draw them up weak. In order to this, let a light frame of lattice-work, reſembling the roof of a houſe, be made, of the breadth and length of the ſtage; and let this be covered with painted canvas, or oiled paper. This roof ſhould be ſupported by poſts fixed up in proper parts of the ſtage; and of a ſufficient height to admit the flowers being viewed with pleaſure, and at the ſame time to defend the flowers from wet, and the ſcorching rays of the ſun.

Lay Carnations and Double Sweet-Williams.

You may continue to lay carnations and double ſweet-williams, during the whole month; but the ſooner it is done the better. The ſame method laid down in the preceding month muſt be purſued.

Remember to refreſh your layers often with water in dry weather; and where you perceive any of them have ſtarted from their places, let them be again pegged down in their proper poſition.

Tranſplant Carnation Layers.

At the latter end of this month, many of the carnation layers that were laid about the middle of June, will be ſufficiently rooted for tranſplantation.

Let them therefore be looked over, and let ſuch as have ſhot out tolerable roots, be carefully ſeparated from the mother plant. They ſhould be cut off cloſe to the ſlit part of the layer, and planted immediately after cutting off the tops of the leaves.

They may either be planted in ſmall pots, or beds of rich earth. If in the former, the pots muſt be ſet in a ſhady place, and the plants moderately watered from time to time till they have taken freſh root. In theſe pots they are to remain till March, and then removed into larger pots where they are intended to blow.

The beds, in which the layers of common carnations are generally planted, ſhould be three feet broad, the earth well dug, and the ſurface raked very even. In theſe beds the layers muſt be ſet as ſoon as taken from the mother plant, in rows five or ſix inches aſunder, and watered as ſoon as planted.

In theſe beds they are to remain till October, when they are to be taken up with balls of earth about their roots, and planted in the borders where they are to flower. But remember, during the interval, to weed and water the beds occaſionally.

Management of tender Annuals.

Let your cockſcombs, tricolars, double-balſams, and other curious annuals, kept till this ſeaſon under glaſſes be now brought out; remembering to clean the plants from all decayed leaves, to ſtir the earth a little at the top of the pots, and to add a ſprinkling of ſifted earth over it.

Remember alſo to ſupport every plant with a ſtick of a proper height, fixed in each pot, and to let the ſtem of the plant be tied neatly to it in different places.

When this is done, let a moderate quantity of water be gently poured over the head of the plant. This will at once refreſh the plant, cleanſe the leaves from duſt, and give it a very lively appearance.

Remember to place them where they are to remain, and to ſupply the plants duly with water in dry weather.

Tranſplant common Annuals.

If any of your common annuals ſtill remain in the ſeed or nurſery-beds, let them be tranſplanted at the beginning of this month. But remember to take them up with balls of earth about their roots, and to plant them in the places where they are to remain.

As ſoon as they are planted, let them be refreſhed with water, and ſuch as have long ſtems be ſupported with ſtakes.

Remove Perennial Plants.

All your perennial and biennial plants, particularly wall-flowers, ſtock july-flowers, ſweet-williams, columbines, Canterbury and pyramidal bell-flowers, Greek valerian, tree primroſe, ſingle ſcarlet lychnis, roſe campions, French honey ſuckles, hollyhocks, &c. that ſtill remain in their ſeed-beds, muſt now be removed into nurſery beds.

In order to this, let ſome beds of rich earth, three feet and a half broad, be now prepared; and the plants taken up and ſet immediately, each ſort ſeparate, in the nurſery-beds. Each bed will contain ſix rows, and the plants muſt be ſet about ſix inches aſunder in the rows.

Remember to water the plants as ſoon as they are ſet, and to repeat the waterings occaſionally, till they have taken root.

Tranſplant Seedling Auriculas and Polyanthuſes.

It is now time to remove your ſeedling auriculas and polyanthuſes from their ſeed-beds.

In order to this, let a ſpot of ground, well defended from the mid-day ſun, be choſen, neatly dug, and the ſurface raked very even.

This being done, let the plants be taken up, and immediately ſet, about four inches aſunder every way in theſe beds, cloſing the earth well about them, and refreſhing them gently with water.

Remember to keep the beds clear from weeds, and to refreſh them with water every two or three days, in dry weather, during the ſummer ſeaſon.

Propagate Scarlet Lychnis, &c.

You may ſtill propagate ſcarlet lychnis, and other plants of that kind, by cuttings, in the manner laid down in June. But remember to do it at the beginning of the month, leſt they have not time ſufficient to ſhoot out proper roots before the cold weather comes on.

Management of Auricula Plants in Pots.

Examine often your choice auricula plants in pots, taking away all dead leaves as faſt as they appear, and pulling up every weed.

Remember not to omit watering your plants pretty frequently in dry weather.

Take up Bulbous Roots.

Your crown imperials, red lillies, bulbous iris's, and narciſſus's, with ſeveral others of the ſame kind, will be now paſt flowering, and their leaves in a decaying ſtate. Let them therefore be taken up in a dry time, and after ſeparating the off-ſets from the principal, the latter may be either planted again immediately, or properly dried, cleaned, and preſerved, till October or November, and then planted regularly in the borders.

The ſmall off-ſets ſhould be planted by themſelves in a nurſery-bed, for a year or two, to gather ſtrength, and then be planted among other bulbous roots in beds or borders.

Trim Flowering Shrubs and Ever-greens.

Let all the rude ſtraggling branches on your flowering ſhrubs and ever-greens, be now cut off with a knife. By this means the head of each plant will be formed in a regular manner, and every ſhrub ſtand ſeparate and diſtinct.

Support Flowering Plants.

Look over your flowering plants, and wherever you perceive a ſupport neceſſary, let a ſtake be fixed in the earth, and the ſtem of the plant tied to it.

If this be done early, few of your plants will be broken by the wind or rain, which would otherwiſe be the fate of many.

Cut down decayed Flower Stems.

Many of your perennial fibrous-rooted plants will now be paſt their bloom; let their ſtems therefore be cut down cloſe to the head of the plant, and all the dead leaves cleared away.

Clip Hedges.

If you would have your hedges perfectly neat, they ſhould be clipped at the beginning of this month, and a ſecond time about the middle of Auguſt; but if you think one clipping ſufficient, it will be better to defer it till the latter end of this month, or the beginning of Auguſt.

Cut Box Edgings.

Your box edgings that were not trimmed laſt month, muſt be trimmed now. But remember to do it in a moiſt time; for when box is cut in dry weather, it will turn brown, and make a very unſightly appearance.

Box edgings ſhould never be ſuffered to grow higher than three or four inches, nor broader than two and a half.

Deſtroy Weeds in the Borders.

Remember to keep your borders, eſpecially thoſe next the walks, intirely free from weeds; and be ſure not to let any of them ripen their ſeed in any part of the garden.

As ſoon as you have hoed the borders, let them be immediately raked, in order to draw off the weeds and all other litter; for this will make the ſurface ſmooth and even, and give the whole a neat and pleaſing appearance.

Mow Graſs-Walks and Lawns.

Your graſs-walks and lawns ſhould be regularly mown about once a week, which will keep the graſs in general in tolerable good order.

Remember, likewiſe, to roll your graſs now and then; for this will be a great addition to the beauty of the plats and walks, and, at the ſame time, render the ſurface firm and even.

Gravel-Walks.

Your gravel-walks will require ſome care. They muſt be rolled twice a week, at leaſt, if they are intended to be kept any thing neat. Nor muſt any weeds be ſuffered to grow, or any ſort of litter be ſeen upon them.

AUGUST.

Work to be done in the KITCHEN-GARDEN.

Cucumber Plants.

YOUR cucumber plants will, at this ſeaſon, demand particular attention, eſpecially thoſe which are ſown in the open ground, to produce fruit for pickling.

Theſe plants muſt be well ſupplied with water in dry weather; they will require it three or four times a week, at leaſt. And it ſhould be remembered, that the quantity of fruit will greatly depend on this circumſtance.

The young fruit ſhould be gathered about three times a week; for when once the fruit have attained a proper ſize, they will ſoon be too large for pickling. Let the

vine

vines be carefully looked over, in a regular manner, every other day.

Ripening Melons.

It will be neceſſary to take particular care of your ripening melons; for if too much rain ſhould happen to fall at this time, it would, in a great meaſure, deſtroy the fruit, unleſs properly defended. Let, therefore, both the roots and fruit be ſheltered by the methods mentioned laſt month.

Sow Winter Spinnage.

If the ſeed for a full crop of ſpinnage was not ſown laſt month, it muſt be done at the beginning of this.

Let therefore a piece of rich ground, that lies tolerably dry in winter, be neatly dug, the ſeed ſown immediately, trod in, and the ſurface raked even.

As ſoon as the plants have got leaves about an inch broad, ſet them be thinned and cleared from weeds. This may be done either by the hand or hoe, obſerving to thin the plants regularly, leaving them at about four inches from one another. This will give them proper room to ſpread, and gather ſtrength ſufficient to enable them to endure the cold.

It ſhould alſo be remembered, that when ſpinnage is allowed room to ſpread itſelf regularly, the plants will produce very large and thick leaves, far ſuperior to thoſe found on plants crowded too near one another.

Sow Cabbage Seed.

Between the ſixth and twelfth of this month, is a proper ſeaſon for ſowing early cabbage ſeed, particularly the ſugar loaf, or early Batterſea kinds.

In order to this, let an open ſpot of rich ground be dug, and divided into beds three feet and a half broad. Sow the ſeed moderately thick, and rake it in lightly with an even hand.

Other kinds of cabbage ſeed, particularly that of the long-ſided cabbage, may alſo be ſown at the beginning of the month.

Sow Cauliflowers.

Between the eighteenth and twentieth of this month, a little cauliflower ſeed ſhould be ſown for raiſing plants to produce an early crop next ſummer; and about a week after ſow for the main crop.

The plants raiſed from the firſt ſowing ſhould be planted out for good about the latter end of October, under hand or bell-glaſſes. Some of the plants may, at the ſame time, be ſet under a ſouth wall, where they will often endure the winter without any other ſhelter.

With regard to the plants raiſed from the ſecond ſowing, and intended for the main crop, they ſhould, for their more certain preſervation, be planted under frames about the laſt week in October, and continue there during the whole winter.

The ſeed muſt be ſown in a ſpot of clean rich ground neatly dug, and divided into beds three feet and a half broad. As ſoon as the ſeed is ſown, let it be raked in very carefully; or about a quarter of an inch thick of light earth be ſifted over it. In dry weather, the bed muſt be moderately watered from time to time, both before and after the plants appear. By this means the plants will ſoon come up, riſe equally, and all take a regular growth.

Tranſplant Broccoli.

At the beginning of this month, let a ſpot of open ground be prepared for planting out the ſecond crop of broccoli. If a little rotten dung be ſpread over the ground, and well dug in, it will prove of the greateſt advantage to the plants.

Theſe broccoli plants ſhould be planted in rows two feet aſunder, and twenty inches apart in the rows. Remember to give them a little water as ſoon as planted.

With regard to the broccoli planted out laſt month, you muſt now remember to draw the earth about their ſtems; for this will greatly ſtrengthen them, and promote their growth.

Tranſplant Savoys.

This is a very good ſeaſon for tranſplanting ſavoys, for the plants will be in exceſſent order for the table ſoon after Chriſtmas. Let them be ſet in rows eighteen or twenty inches aſunder, and the ſame diſtance be allowed between the plants in the rows.

Tranſplant Celery.

More celery muſt be tranſplanted at this ſeaſon. Let therefore an open ſpot of ground be choſen, and the trenches prepared in the manner directed laſt month. In theſe trenches, let the plants (after trimming the ends of their roots, and cutting off the tops of their leaves) be ſet four or five inches diſtant, in a ſingle row along the middle of each trench. Remember to water them as ſoon as they are planted, and, if the weather prove dry, to repeat the operation every evening, till the plants have taken root.

Earth up Celery.

As your celery planted in the trenches during the two laſt months advances in height, let it be earthed up. But remember to do this in dry weather, and when the plants are alſo dry. The earth muſt be well broken, and then laid up lightly to the plants.

They muſt be earthed up to a proper height on each ſide; but, at the ſame time, particular care muſt be taken not to break down their leaves, or bury their hearts.

Tranſplant Endive.

Another parcel of endive muſt be now tranſplanted. In order to which, let an open ſpot of ground be properly dug. When this is done, draw up ſome of the ſtrongeſt plants, trim the extremities of their roots, take off the tops of their leaves, and plant them twelve inches from one another every way.

Remember to water them as ſoon as planted, and, if the weather be dry, to repeat the waterings every two or three days, till the plants have taken root.

Blanch Celery.

Towards the latter end of this month, the endive planted out in June will be full grown, and ſhould therefore be tied up to promote their blanching.

When the weather is dry, let the plants be examined, and the leaves of ſuch as are proper for blanching be tied up with freſh baſs. Remember to gather the leaves up regularly in your hand, and to tie them together in a neat manner, but not too ſtraight.

Sow Turneps.

A late crop of turneps may ſtill be ſown; and if it be done the firſt or ſecond week in the month, there will be very little danger of ſucceſs; but after that time it is not prudent to ſow turneps, for they generally miſcarry.

Hoe and thin Turneps.

The turneps ſown laſt month muſt now be hoed and thinned. But remember to take the advantage of dry days, and to do it before the plants are too far advanced in their growth: the time may be known by examining the plants; for when their rough leaves are about the breadth of a man's thumb, the work may be done with expedition and regularity. Six or eight inches ſhould be allowed between the plants.

Sow Onions.

If you omitted to ſow for ſpring onions laſt month, let it be done at the beginning of this; by the ſecond week at fartheſt.

In order to this, let a clean dry ſpot of ground be neatly dug, and divided into beds three feet and a half, or four feet broad. On theſe beds let the ſeed be ſown tolerably thick, but as equal as poſſible, and raked in with a very even hand, that the plants may riſe regularly in all parts of the beds.

It will be prudent to ſow, at the ſame time, a little Welſh onion-ſeed, that if the former ſhould be deſtroyed by the froſt, the latter, which will ſurvive almoſt the ſevereſt winter, may ſupply its place.

The Welſh ſeed ſhould be ſown in the ſame manner as the Engliſh; ſo that the inſtructions given for the latter will be equally ſufficient for the former.

Take up Onions.

Examine your crops of onions; and when you perceive their leaves begin to fall, and wither, the roots have acquired their full growth, and muſt therefore be taken out of the ground. But remember to do this in dry weather, and to ſpread them immediately in the ſhade to dry, as directed laſt month.

Take up Garlick and Shallots.

Your crops of garlick and ſhallots muſt alſo be taken out of the ground when their roots have acquired their full growth, which is known by their leaves, which always begin to wither as ſoon as the roots have done drawing nouriſhment.

Sow Carrots.

About the third or fourth week in this month, but not before, a little carrot ſeed may be ſown, in order to raiſe plants for ſpring uſe. Let the ſeed be ſown in beds, not too thick, and raked in regularly. The plants raiſed from this ſowing will ſupply the table in the ſpring.

Sow Raddiſhes.

A little raddiſh ſeed, of the ſalmon or ſcarlet kind, may be ſown at two different times this month; about the middle, and towards the latter end. The plants from the former will be fit to draw about the middle of ſeptember, and thoſe from the latter about Michaelmas, and continue tolerably good all October.

Remember to ſow the ſeed in an open ſpot of ground, and to water the bed now and then in dry weather.

Sow Lettuce Seed.

A ſmall quantity of the ſeeds of coſs, Sileſia, brown Dutch, and common lettuce, ſhould be ſown at two different times this month. Let the firſt ſowing be performed before the tenth of the month, and the ſecond between the eighteenth and twenty-fourth. The plants from the firſt will ſupply the table in October and November; but the plants from the ſecond are to be removed into warm borders, in order to ſtand the winter, and ſupply the table in April and May.

Remember to ſow the ſeeds of each ſort ſeparate, to rake them in evenly, and to water the beds now and then in dry weather.

Some of the plants raiſed from the ſeed of the ſecond ſowing, particularly the brown Dutch and cabbage lettuce, may, when fit, be planted in ſhallow frames, where they muſt be covered every night, and in all wet, or other bad cold weather, with the glaſſes: in hard froſt they muſt alſo have coverings of dry ſtraw, fern, &c. laid over the glaſſes, and about the outſides of the frames. By this means they will be tolerably well cabbaged by February, when they will be conſidered as a very great rarity.

Tranſplant Lettuces.

Some of the lettuces ſown laſt month, to ſupply the table in autumn, muſt be now tranſplanted.

In order to this, let a ſpot of rich ground, in a dry ſituation, be prepared, and the lettuces planted in it immediately, ten or twelve inches aſunder every way. Remember to water them as ſoon as planted, and to repeat the operation occaſionally, in dry weather, till they have taken root.

Sow ſmall Salleting.

A ſmall quantity of the ſeeds of muſtard, raddiſh, creſſes, rape, and turnep, ſhould be ſown once every week, if a regular ſupply of ſome ſalleting herbs be wanting.

A ſhady border muſt be choſen for this purpoſe, where the ſeeds are to be ſown, each ſort ſeparate, in ſhallow drills, and covered with dry earth about a quarter of an inch thick. Remember to water them occaſionally in dry weather.

Thin Colewort Plants.

About the middle, or latter end of the month, look over your colewort plants ſown laſt month; and wherever you perceive they ſtand too thick, let ſome of them be drawn out, and tranſplanted in rows twelve inches aſunder, and the plants ſix inches apart in the rows.

By this means, the plants remaining in the ſeed-bed will have more room to grow, and thoſe taken up and tranſplanted will be fit for uſe three or four weeks ſooner than if they had been left in the ſeed-bed till next month.

Clean Aſparagus Beds.

Remember to clear your beds of aſparagus from weeds and litter of every kind, particularly thoſe that were planted laſt March or April.

At

At the ſame time, let the ſeedling aſparagus ſown in the ſpring be kept very clean; a careful hand-weeding will beſt anſwer this purpoſe.

Examine Artichoke Plants.

Your artichoke plants ſet in March or April muſt be now examined, as many of them will be in fruit; and beſides the principal, or top artichoke, there will riſe many ſmall heads, or ſuckers, from the ſides of the ſtems; but all theſe ſhould be diſplaced, if you deſire the principal head to be large. It will, however, be neceſſary to take theſe off before they exceed the ſize of an egg, otherwiſe they will have exhauſted too much of the ſtrength of the root; and, conſequently, render the principal head proportionably ſmaller.

It may not be amiſs to repeat the caution mentioned laſt month, of breaking down the ſtems of the artichokes when you cut the fruit.

Propagate Sweet Herbs.

The ſlips of many of the aromatic herbs, particularly thoſe of ſage, hyſſop, maſtich, marjoram, lavender, rue, and roſemary, may ſtill be planted, for they will ſucceed, if planted in the beginning of the month.

The ſlips muſt be from ſix to nine inches long, and planted in a ſhady border. Remember to put two-thirds of the ſlip into the ground, and to water them occaſionally in dry weather.

Trim Aromatic Herbs.

The decayed flower-ſtems of hyſſop, ſavory, lavender, and other aromatic plants of that kind, ſhould be cut down, and all the ſtraggling and other young ſhoots ſhould be ſhortened at the beginning of this month.

But remember to do this in a moiſt time, if poſſible. The flower-ſtems, and young ſhoots, ſhould be cut pretty cloſe, with a pair of garden-ſhears. This will make them put out numbers of freſh ſhort ſhoots, ſo that they will form cloſe ſnug heads before winter, and appear neat during that dreary ſeaſon.

Gather Herbs to dry and diſtil.

Let the herbs intended to ſerve the family in the winter be cut down in a dry day, and ſpread to dry in an airy room, out of the reach of the ſun. When thoroughly dried, let them be tied in bunches, and hung up in a dry room for uſe.

This is alſo the ſeaſon for cutting down many plants for diſtillation. But remember to do it when they are in flower, for then they are in their full prime.

Gather Seeds.

As young ſeeds ripen, let the heads or pods be gathered in a dry day; and as ſoon as they are cut let them be ſpread on mats or cloths, to dry and harden, in a ſhady place, where no rain can touch them. In about a fortnight the heads or pods will be ſufficiently dry, and the ſeed ſhould therefore then be beaten or rubbed out, and well cleaned.

When you have thus procured clean ſeed, let it be ſpread upon cloths in a dry but ſhady place, for a day or two, to harden, and then put up in bags or boxes for uſe.

Deſtroy Weeds.

You muſt be very careful, at this ſeaſon, to deſtroy the weeds, among all your crops. Be ſure never to let them get to any great head; nor any of them ever ripen their ſeed. This care muſt be extended to every part of the garden, whether cropped or not.

By this means you will keep the weeds under; for it ſhould be remembered that every weed ſuffered to ripen its ſeed, will lay a foundation for hundreds the year to come. No care therefore ſhould be wanting to deſtroy them before they arrive at maturity.

In open ſpots, and wherever there is room to uſe a hoe, this is eaſily done; but remember to let your hoe be ſharp, and let it be done in a dry day.

When you have hoed down the weeds, do not ſuffer them to lie on the ground where they grow, but rake them up, and carry them away.

The NURSERY.

Tranſplant Seedlings.

Examine the buds of your ſeedling plants, particularly thoſe of the pine, fir, and box; and wherever you perceive the plants crowded too cloſe together, let ſome of them be drawn up and tranſplanted, obſerving the ſame directions that were given laſt month. For though this is not the ſeaſon for making a general tranſplantation; yet where the plants ſtand too cloſe together, ſome of them ſhould be removed, therwiſe they will ſpoil one another.

Prepare Ground for Tranſplanting.

About the latter end of this month, it will be time to begin trenching ſuch pieces of ground as are intended to be planted in autumn, with any kind of trees or ſhrubs. The ground ſhould be well dug and laid up in high ridges, that it may enjoy every poſſible advantage from the rains, ſun, and dews.

Remember to keep the whole ſpot free from weeds; cutting them up with the hoe as ſoon as they appear, and carrying them off the ground.

Trim Ever-greens and Foreſt Trees.

This is a proper ſeaſon for trimming ever-greens and ſuch other ſhrubs in the nurſery, that appear to want it. Remember to cut away the vigorous ſhoots, or to ſhorten them ſo as to form a more regular head.

At the ſame time examine your foreſt-trees, and wherever you perceive they have made any vigorous ſhoots from their ſtems near the roots, let ſuch ſhoots be cut off cloſe.

Bud Fruit-Trees.

The operation of budding may ſtill be performed on ſome ſorts of fruit-trees, provided it be done at the beginning of the month.

You muſt alſo now look over the ſtocks that were budded three weeks or a month before, in order to untye the baſs, that the parts about the bud may not be pinched.

Weed and Water Seedling Plants.

Remember to keep your beds of ſeedling plants entirely free from weeds; and to water them occaſionally in dry weather.

Deſtroy Weeds.

Let the ſpaces between the rows of all kinds of young trees and ſhrubs be deſtroyed. Remember to do this work in dry days; and when the weeds are ſo cut down with the hoe, to rake them up, and carry them away; for otherwiſe many of the larger weeds would take freſh root, and grow up again.

The FRUIT-GARDEN.

Wall Trees.

Your peach, nectarine, and other trees of that kind ſtill require attention. It will be neceſſary to look them once more carefully over, and wherever you find any of the branches diſplaced by the wind or other accident, to nail them again in a neat and ſecure manner.

At the ſame time take away all the ſtraggling ſhoots that have been lately produced, for they will only tend to hinder the ripening of the fruit.

Vines.

You muſt once more look over your vines, whether planted in vineyards, or againſt walls, in order to diſplace every ſhoot that has been lately produced, whether from the old or young wood; for they are all not only entirely uſeleſs, but will tend greatly to retard the growth and ripening of the fruit.

At the ſame time examine carefully all the bearing or other proper ſhoots; and wherever you perceive any of them ſtarted from their places, faſten them again to the wall or ſtakes, in their proper direction. By this means, every bunch of fruit will ripen equally, for every one will enjoy equally the advantages of the ſun and air.

It will alſo be proper to examine the fruit, and wherever you find the branches entangled either with one another or with the ſhoots, let them be relieved, ſo that every bunch may hang in its proper poſition.

Fig Trees.

The figs will be now full grown and begin to ripen; conſequently a proper ſhare of the ſun will be neceſſary to give them a flavour.

In order to this, let all the young ſhoots be now laid in cloſe to the wall; taking care to uſe the knife at this ſeaſon as little as poſſible. Let therefore no ſhoots, except thoſe which are produced foreright, be now cut off; laying in all the fair growing ſide-ſhoots to produce fruit next year. And as theſe trees produce their fruit upon none but ſhoots of one year old, it is the ſafeſt way to leave enough of them at this ſeaſon; for all that are not wanted to lay in at the general ſeaſon of pruning, may then be cut away.

But whatever you do with regard to theſe ſhoots, be ſure not to ſhorten them; they muſt be laid in at their full length; for the ſhoots of theſe trees muſt never be ſhortened.

Remember to lay them in regularly, not acroſs one another, and ſo ſecure them properly, for the broad leaves of theſe trees give the wind and rain great power over them.

Bud Trees.

You may ſtill perform the operation of budding with ſucceſs, provided it be done at the beginning of the month. The ſame method muſt be purſued as is given in the work of the nurſery for June.

Examine Budded Trees.

It will be neceſſary to look over your trees that have been budded about three weeks or a month, in order to looſen the bandage; for if this be neglected, the motion of the ſap will be greatly impeded, the parts about the bud will ſwell irregularly, and four out of five of the buds will miſcarry.

At the ſame time remember to examine the part of the ſtock below the bud, and rub off all the ſhoots produced in that part.

Defend Wall Fruit from Birds, Inſects, &c.

Your choice wall-fruit will ſtill want your care to defend it from birds, inſects, &c.

The former may be effectually kept off by fixing up nets before the trees whoſe fruit they are fond of. This precaution therefore ſhould not be omitted; particularly with regard to grapes, figs, and late cherries.

With regard to waſps, flies, and hornets, the beſt method is that mentioned laſt month, namely, by fixing phials filled with ſugar-water, on proper parts of the tree; for the ſweetneſs of the water will allure the inſects from the fruit, and induce them to crawl into the bottles, where they will be drowned.

Cleanſe the Borders about Fruit Trees.

No weeds ſhould be ſuffered to grow, or litter of any kind to lie, on fruit-tree borders.

The keeping theſe borders clean will be attended with a double advantage; the trees will not be deprived of their nouriſhment; and at the ſame time, the clean ſmooth ſurface of the ground will reflect the ſun's heat upon the tree, and conſequently promote the ripening, and improve the flavour of the fruit. Add to this, the agreeable pleaſure the eye will receive from the neatneſs of the borders.

Deſtroy Weeds.

Remember to deſtroy all the weeds between the rows of vines in the vineyard; let them be cut down as ſoon as they appear; and when this is done, let them, together with all other kind of litter, be taken away.

This will greatly promote the growth and ripening of the grapes; for a perfectly clean ſurface in a vineyard, anſwers in ſome degree the purpoſe of a wall, by reflecting the ſun's heat upon the vines and fruit.

But were the weeds permitted to grow, no heat could be reflected from the ſurface. On the contrary, a moiſt vapour would ariſe from the intervals between the rows, which would greatly retard the growth and ripening of the grapes; beſides robbing the roots of great part of their nouriſhment.

The PLEASURE or FLOWER-GARDEN.

Management of Carnations and Sweet William Layers.

All thoſe carnation layers that were layed five or ſix weeks ago, will now be well rooted, and ſhould therefore be cut from the original root, and tranſplanted into beds or pots. The choiceſt kinds ſhould be planted in pots, that they may be more eaſily defended from the cold of the winter.

In order to this, let a quantity of penny or half-penny pots be procured, and filled with good earth.

This

This being done, take off the layers, trim their tops a little, cut off the bottom of the ſtalk cloſe to the ſlit part, plant one layer in each pot, and immediately give it a little water.

When all are planted place the pots in a ſhady ſituation, and water them occaſionally till they have all fairly taken root.

As ſoon as you perceive the plants are firmly rooted, let the pots be removed into a more open ſituation, and there remain till the latter end of October. At that time a bed of dry compoſt ſhould be prepared, of the breadth and length of a common frame: the bed muſt be compoſed of dry and light earth well mixed with coal aſhes, and raiſed at leaſt four inches above the level of the ground. When the bed is thus prepared put on the frame, and plunge the pots up to their rims in the compoſt, and as near together as may be; for here the plants are to remain all the winter, and to be defended in ſevere froſts, ſnow, and heavy rains with glaſſes; but in dry and mild weather the glaſſes muſt be taken away.

By this means the plants will be effectually preſerved from froſt, which cannot enter at the ſides of the pots to hurt the roots.

If a frame and glaſſes be wanting, the pots may be plunged in a bed prepared as above, and effectually defended by fixing hoops acroſs the bed, and covering them with thick mats in bad weather.

In this bed the plants are to remain till the latter end of February, or the beginning of March, when they are to be turned out of the ſmall pots with balls of earth about their roots, and planted in larger, where they are to blow.

With regard to the common carnation layers intended to blow in the borders, they ſhould be managed as follows:

As ſoon as the layers are well rooted, they are to be ſeparated from the old roots, and trimmed as above directed; and then planted in a bed or border of rich earth. They ſhould be ſet at leaſt ſix inches aſunder every way, watered immediately, and the operation repeated occaſionally till they have taken root. Remember alſo to ſhade them from the ſun till they are well rooted.

In this bed or border the layers are to remain till October; and then tranſplanted into the borders where they are to flower.

The layers of double ſweet-williams that were layed five or ſix weeks ago, muſt be now taken from the old roots, and managed in the ſame manner as the layers of carnations.

Propagate Fibrous-rooted Plants.

This is a proper ſeaſon to increaſe many of the double flowering fibrous rooted plants, particularly the double roſe campion and catchfly, double ſcarlet lychnis, and double rocket, double ragged robin, batchelors button, &c. by parting their roots, which is done in the following manner:

Where the plants have grown into large tufts, let the whole of each root be taken entirely out of the earth. When this is done let it be divided, taking care that every plant or ſlip ſo ſeparated, be properly furniſhed with roots.

The root being thus parted into ſeveral ſlips or diſtinct plants, let the ends of the roots of every ſuch ſlip or plant be cut off, and all the dead and broken leaves taken away.

As ſoon as your plants are thus prepared, let them be planted in a ſhady border, or where they can be occaſionally ſhaded with mats, about ſix inches apart. Remember to cloſe the earth well about them, and to give them a little water. Some of the ſtrongeſt ſlips may be immediately planted again in the borders.

They will ſoon take root, if occaſionally watered, and by the latter end of October have acquired ſtrength ſufficient to be removed, when they are to be taken up with balls of earth about their roots, and planted ſome in pots, and the reſt in borders: they will all flower next ſummer.

Sow the Seeds of Auriculas and Polyanthuſes.

Auricula and polyanthus ſeed may now be ſown, in boxes or large pots. Let therefore ſome pots or boxes be filled with light earth, about the middle or latter end of the month. On the ſurface of this mould let the ſeed be ſown pretty thick, and covered about a quarter of an inch deep.

Remember to place your pots or boxes where the ſeed may have the benefit of the morning ſun, and let them continue there till the latter end of next month, when they are to be removed into a ſituation where the mid-day ſun may ſhine upon them.

Sow the Seeds of Bulbous-rooted Flowers.

About the latter end of the month you may ſow the ſeeds of tulips, hyacinths, narciſſus's, iris's, crown imperials, frutillarias, lillies, martagons, crocuſſes, and other bulbous-rooted flowers.

It will be much the better method to ſow theſe ſeeds in boxes, rather than in beds, becauſe the former may eaſily be removed to any ſituation. Theſe boxes ſhould be about fifteen or eighteen inches broad, and ten or twelve deep, and filled within half an inch of the top with fine rich earth raked very fine and even.

On the ſurface of this earth let the ſeed be ſown moderately thick, and covered about half an inch deep with ſifted earth.

When the ſeed is thus ſown, let the boxes be removed into a ſhady ſituation, and, if the weather prove dry, lightly watered now and then. In this place they are to continue till the latter end of September, when they muſt be removed into a warmer ſituation.

But if you have not boxes for this purpoſe, the ſeed may be ſown in beds of light earth, about three feet broad, and ſituated in a dry and warm part of the garden.

You muſt however remember to defend the plants, whether ſown in beds or boxes, from ſevere froſts and ſnows, by laying dry litter on the ſurface of the beds, and outſide of the boxes.

About the latter end of next March the plants will begin to appear, and muſt be kept clear from weeds, and refreſhed often with water in dry weather.

Sow the Seeds of Anemonies, Ranunculuſes, &c.

The ſeeds of anemonies, ranunculuſes, and ſpring cyclamons may now be ſown; but it ſhould be done in boxes or wide-mouth pots, filled with rich light earth.

The

The ſeeds ſhould be ſown pretty thick on the ſurface, and covered about a quarter of an inch thick with ſifted earth.

Remove Bulbous Roots.

The roots of crown imperials, martagons, red lillies, bulbous and Perſian iris's, narciſſuſes, ſpring crocuſſes, jonquils, and fritillarias, may now be taken up, and the off-ſets ſeparated from them.

When this is done the principal roots may either be planted again in their proper places, or dried, cleaned, and put up till October, and then planted.

With regard to their off-ſets, the beſt of them at leaſt, ſhould be planted in nurſery-beds, each ſort ſeparate, and remain there a year or two.

Tranſplant Perennials.

The ſeedling wall ſtocks, ſweet-williams, columbines, ſcabiouſes, and other perennial and biennial plants, which ſtill remain in the ſeed-bed, muſt be now tranſplanted into nurſery beds.

But remember to let it be done in moiſt weather, and the ſooner in the month the better; becauſe the plants will have more time to root and get ſtrength before winter.

Let them be planted in beds about ſix inches diſtance from one another every way, and directly watered.

After ſtanding about two months, they muſt be tranſplanted from theſe beds into the places where they are to remain.

Trim flowering Plants.

Remember to look over all your flowering plants, and wherever you perceive any branches advance in an irregular and ſtraggling manner, let them be either cut off cloſe, or ſhortened. And where the ſhoots of different branches interfere with one another, let them be ſhortened, that every branch may ſtand ſingle; for flowers always appear to greater advantage when they ſtand clear of each other, than when they are blended together.

Let the main ſtems be well ſupported with ſtakes, and all the withered and decayed leaves pulled off.

All the ſhoots produced near the ground by ſtrong branching annual flowers, ſuch as French and African marigolds, &c. ſhould be cut away, and a foot at leaſt of clear ſtalk left above the ſurface. By this means the plants will form handſome and regular heads, the flowers will have more liberty to grow, and ſhow themſelves to much greater advantage.

Gather Flower-Seeds.

The ſeeds of ſuch flowers as are now ripe ſhould be gathered in a dry day; and ſpread to dry in an airy ſhady place.

As ſoon as they are ſufficiently hardened let them be beat or rubbed out, and preſerved for uſe in bags or boxes.

Cleanſe the Borders from Weeds, &c.

Remember to keep the borders exceeding neat, and free from weeds. In order to which they ſhould be frequently gone over with a ſharp hoe, to looſen the ground, and cut up the weeds as they appear.

When this is done, let them be neatly raked, in order to draw off all the weeds and other litter, and to lay the ſurface ſmooth and even.

Clip Hedges.

This is the moſt proper ſeaſon for clipping your hedges of holly, yew, hornbeam, elm, lime, thorn, &c. provided you trim them but once in the year, for they will not now puſh out any more branches of conſequence this ſummer.

And thoſe which were clipped about the beginning or middle of laſt month, will want clipping again about the middle or latter end of this.

Cut Box and Thrift Edgings.

This is alſo a proper ſeaſon for cutting box and thrift edgings; but remember to do it in moiſt weather, and not to let thoſe of box grow too broad.

The decayed flower ſtalks of your thrift edging ſhould now be cut off, and where the ſides have grown uneven they ſhould be reduced to order with a pair of garden ſheers, ground very ſharp at the points.

Water Annual and Perennial Plants.

Remember to water your annual and perennial plants frequently in dry weather: thoſe of the former preſerved in pots, will require it three or four times a week.

At the ſame time let all the dead leaves on your annual plants be taken off; and the ſtalks of thoſe perennial plants that have done blowing be cut down, a little of the old earth taken from the ſurface and replaced with freſh, and the pots ſet in a ſhady place.

Mow Graſs Walks and Lawns.

It will be neceſſary to continue the mowing of graſs walks and lawns, once a week at leaſt.

It will be alſo neceſſary to poll and roll them frequently; for otherwiſe the worm-caſts and other protuberances on the ſurface will greatly impair their beauty.

Gravel Walks.

Remember to keep your gravel walks entirely free from weeds and other litter, and to roll them twice a week at leaſt.

SEPTEMBER.

Work to be done in the KITCHEN-GARDEN.

Cauliflowers.

ABOUT the middle or latter end of the month it will be time to remove the cauliflower plants ſown in Auguſt, into a nurſery-bed.

In order to which let a bed be made in the manner deſcribed laſt month, in a well ſheltered part of the garden open to the ſun, for their reception.

As ſoon as the bed is finiſhed, draw up ſome of the beſt plants from the ſeed-bed, clear them from decayed or damaged leaves, and plant them in rows about three inches aſunder, allowing the ſame diſtance between the

plants in the rows. Remember not to plant them ſo deep as to bury their hearts, for that would inevitably deſtroy them.

Give the plants a little water to ſettle the earth about their roots, as ſoon as they are ſet; but be ſure not to pour the water upon them too haſtily, leſt you break their leaves, or waſh the earth into their hearts.

The plants being thus ſet, put on the frame and glaſſes for a few days till the plants have taken root, remembering to ſhade the plants from the rays of the ſun; when the glaſſes are to be removed, and only applied in very heavy rains, during an interval of a month at leaſt.

Michaelmas Cauliflowers.

About the end of this month, ſome of the cauliflowers planted out in July for a Michaelmas crop, will begin to ſhow their flowers. The plants muſt therefore be encouraged as much as poſſible, by hoeing between, and drawing the earth up round the ſtem of each plant, and keeping them entirely free from weeds.

At the ſame time remember if the weather proves dry, to form the earth like a baſon round each plant, and pour water therein; for this will ſo greatly encourage their growth, that they will produce large heads in October and November. Whereas their heads would have been ſmall at the proper ſeaſon, had the plants been denied a ſufficient degree of moiſture.

Broccoli.

During the firſt or ſecond week in this month, your laſt crop of broccoli muſt be tranſplanted into the place where they are to produce their heads.

In order to this, let a rich ſpot of ground be dug for theſe plants in a warm ſituation, and the broccoli planted in rows a foot and a half aſunder, allowing the ſame diſtance between the plants in the rows.

With regard to the broccoli planted out in the preceding month, they want no other care than that of hoeing the ground, and deſtroying the weeds between the rows, and of drawing up the earth round the ſtems of the plants.

Cabbage Plants.

About the middle of this month, the cabbage-plants ſown the ſecond week in Auguſt, for an early crop next ſummer, muſt be pricked out into nurſery-beds.

Let, therefore, a piece of good ground, in a ſheltered ſituation, be dug for that purpoſe, and laid out in beds three feet and a half wide.

When the beds are ready, thin out the beſt plants regularly in the ſeed-bed, leaving the ſmaller for a fortnight longer; and plant them in rows lengthways of the bed, about four inches aſunder, leaving an interval of ſix inches between the rows. Remember to cloſe the ground well about their ſtems, and to leave the ſurface ſmooth between the plants.

As ſoon as the plants are ſet, give them a little water, and if the weather be dry, repeat the watering two or three times during the firſt week or ten days, when the plants will have taken good root.

Coleworts.

Some time in the beginning of this month, many of the forwardeſt of the colewort plants ſown the latter end of July, will be fit to plant out into the places where they are to remain.

Let therefore a piece of ground be dug for their reception, in a part of the garden where the cutting winds in the winter have the leaſt power; and there planted in rows ten or twelve inches aſunder, and the plants ſix or eight inches apart in the rows.

Turneps.

The turneps ſown the preceding month muſt now be hoed out regularly, leaving them about eight inches diſtant from one another.

Your hoe ſhould be ſharp, and of a middle ſize, that the weeds may be cut up clean.

Spinnage.

The ſpinnage ſown in Auguſt muſt now be cleared and thinned out regularly, to the diſtance of four or five inches, either by the hand or hoe. But remember to leave the ſtrongeſt plants, and to clear the whole bed perfectly from weeds.

If you omitted to ſow ſpinnage laſt month, it may ſtill be done, provided it be not deferred longer than the middle of the month. It will ſucceed tolerably well, if the ſeed be ſown in a rich warm ſoil.

Onions.

Your beds of onions ſown the beginning or middle of Auguſt will now want weeding; for the weeds muſt never be ſuffered to get the ſtart of the plants. This work muſt be done very carefully, and entirely by hand; otherwiſe many of the young plants will be drawn up with the weeds. But the onions need only be thinned, at preſent, except in thoſe places where they riſe in cluſters.

Lettuces.

Towards the latter end of this month, the different ſorts of lettuces ſown in Auguſt, for ſpring uſe, ſhould be planted out where they are to continue.

Let therefore a warm border, under a ſouth wall, or other fence, be prepared for their reception; obſerving, when you dig the ground, to lay the border ſomewhat ſloping to the ſun, and afterwards to rake the ſurface ſmooth and even.

When the border is thus prepared, let ſome of the beſt plants be drawn out of the ſeed-bed, and after trimming the ends of their roots a little, and picking off all the broken or decayed leaves, let them be planted in rows lengthways of the border, about four or five inches aſunder, allowing the ſame diſtance between the plants in the rows.

If the greater part of theſe plants ſurvive the winter, near one half of them may be removed in the ſpring, and planted in a more open expoſure; while the reſt may remain in the border to cabbage early.

It is not yet too late to ſow a little lettuce-ſeed for ſpring uſe, provided it be done in a rich ſpot of ground during the firſt week in the month.

Small Salleting.

The ſeeds of creſſes, muſtard, raddiſh, and rape, ſhould be ſown every week or ten days, in rich, light earth, and in a warm ſituation.

The ſeeds ſhould be ſown in ſhallow drills, and covered about a quarter of an inch deep with light earth.

The ſeed ſown the laſt week in the month, muſt be covered with a frame and glaſſes during the nights, if the weather be cold.

Celery.

A late crop of celery, for ſpring uſe, ſhould be planted out about the middle of this month.

In order to this, let ſome trenches about twelve inches wide, and five or ſix deep, be dug, leaving an interval of two feet and a half between the trenches.

Take up the celery plants, trim their roots and tops, and plant one row in each trench, about four or five inches aſunder.

Earth up Celery.

The rows of celery planted in trenches during the former months, muſt be earthed up. Remember to do it when the plants are dry, to break the earth well, and to lay it properly to the plants, without breaking the ſtalks, or burying the hearts.

Plant Endive.

At the beginning of this month ſome endive muſt be planted out on a dry ſpot, in a warm ſituation, for winter uſe. Let the plants be a foot diſtant from one another every way.

Blanch Endive.

Let the leaves of endive be tied together, when both the weather and plants are dry, in order to blanch it; obſerving to tie up ſuch plants only as have arrived at, or near, their full growth. The leaves muſt be gathered up evenly in the hand, and tied together with a ſtring of baſs.

Cardoons.

By the beginning of this month your cardoons will be advanced to a ſufficient height for blanching. Let therefore their leaves be gathered up, and tied cloſely and regularly together with hay-bands; beginning at the bottom, and winding the bands of hay pretty cloſe together about the plants, as high as you intend to earth them.

When this is done, let the earth be well broke, and laid up about the plants as high as they are tied.

Muſhrooms.

This is the ſeaſon for beginning to prepare the dung, in order to make muſhroom beds.

But it will be neceſſary before the beds are made, to be provided with a proper quantity of the ſpawn, in order to plant in the bed.

The ſpawn of muſhrooms, from which only they are propagated, looks like a white mouldineſs ſhooting out in long ſtrings. It is frequently found among the dung of old hot-beds, or in dung-hills, eſpecially where much litter has been mixed with the dung, and the wet has not penetrated ſo as to rot it. It may alſo be procured by mixing ſome long ſtable-dung, which has not been thrown up in a heap to ferment, with ſtrong earth, and then laying this mixture under cover, where it cannot be wet, and where the air may be excluded from it as much as poſſible; for the more effectually it is kept from air, the ſooner will the ſpawn be produced.

It will generally appear in about two months, if the heap has not laid ſo cloſe together as to heat (for that will deſtroy the ſpawn); and eſpecially if it has been well covered with old thatch or litter, which has lain ſo long abroad as to have loſt the power of fermenting.

Theſe are expedients by which the ſpawn of muſhrooms may be procured almoſt at any time, by thoſe who have not muſhroom-beds in their gardens, and conſequently cannot collect it from their remains: for there are only two months in the year when it can be gathered from downs or paſtures; namely, in Auguſt and September, when muſhrooms ſpring up naturally in many of theſe places.

To procure this ſpawn, the ground ſhould be opened about the roots of muſhrooms, and ſuch earth as is there found full of ſmall white knots, which are the offſets, or young muſhrooms, ſhould be carefully gathered up, ſo as not to break either the lumps or the earth about them. This ſpawn ſhould be kept dry till you have occaſion to uſe it; for the drier it is, the better it will take to the bed, as has been remarkably experienced by Mr. Miller, who declares that he never ſaw thoſe plants produced ſo ſoon, or in ſo great plenty, as from a parcel of their ſpawn, which had lain near the oven of a ſtove for upwards of four months, and was become ſo dry that he deſpaired of its ſucceſs.

When a proper quantity of the ſpawn is procured, let the beds be made of dung, plentifully intermixed with litter, but not thrown in a heap to ferment. The beſt dung for this purpoſe, is that which has lain ſpread abroad for a month or longer.

The breadth of theſe beds ſhould be about two feet and a half at the bottom, and their length proportioned to the quantity of muſhrooms intended to be raiſed.

Theſe beds muſt be made on the ſurface of a dry ſpot of ground, by ſpreading upon it firſt a layer of dung, about a foot thick, and upon this about four inches deep of ſtrong earth; then a couch of dung about ten inches thick, and upon that another layer of earth; contracting the ſurface of the bed all the way till it terminates like the ridge of a houſe. This may be done with three layers of dung, and as many of earth.

When the bed is finiſhed, it ſhould be covered with litter, or old thatch, as well to prevent its drying, as to keep out the wet; and after it has remained eight or ten days in this ſituation, it will be of a proper temperature for receiving the ſpawn.

The bed being thus in readineſs, the thatch or litter ſhould be taken off, the ſides of the bed ſmoothed, and a covering of rich dry earth laid all over it about an inch thick.

Upon this the ſpawn ſhould be placed, by laying it in lumps about two or three inches aſunder, in ſuch a manner as to prevent their ſlipping down; and then the whole covered gently with the ſame light earth as was uſed before, about half an inch deep.

The covering of litter ſhould then be replaced over the bed, ſo thick as to ſecure it from wet, and prevent the drying.

If the weather be temperate, and the ſpawn placed in the beds about the middle of the month, the muſhrooms will come up about the middle of October. Sometimes, indeed, the beds will not yield any muſhrooms for near ſix months after their being planted: but the gardener ſhould not be diſcouraged at this diſappointment; for they will then produce uncommon quantities, and continue in perfection for a long time.

The great art in managing theſe beds, conſiſts in keep-

keeping them conſtantly in a due degree of moiſture, and, above all, not to ſuffer them to receive too much wet; for that would inevitably deſtroy the ſpawn of the muſhrooms.

The muſhrooms produced from theſe beds have a much finer flavour than any gathered in the fields; and if the above directions are obſerved, they may be had in plenty during the whole year: for each ſingle bed will continue good for ſeven months at leaſt; and yield great quantities, if the ſpawn takes kindly.

You ſhould remember, when any of theſe beds are deſtroyed, to take away the ſpawn, and lay it up in a dry place till the proper ſeaſon for uſing it arrives, which ſhould not be ſooner than five or ſix weeks, that it may have time to dry well before it is put into a new bed; for, otherwiſe, there will be ſome danger of its ſucceeding.

The NURSERY.

Dig and Trench the Ground for new Plantations.

This is the ſeaſon for digging and trenching the ground where you intend to plant out a nurſery of young ſtocks for fruit-trees; and alſo where you intend to plant out young foreſt trees, or any kind of hardy ſhrubs.

Tranſplanting.

You may begin to tranſplant, about the laſt week in the month, many of the more hardy kinds of trees and ſhrubs, whoſe leaves are then decayed, eſpecially if the weather be ſomething moiſt.

But if the weather ſhould be very dry, you muſt be ſure to give them a plentiful watering as ſoon as they are tranſplanted.

Several advantages attend the tranſplanting of trees ſoon after the leaves decay; they will have time to take root before the froſt is ſevere enough to prevent it; and by the next ſummer they will be ſo well eſtabliſhed, that the drought of that ſeaſon cannot hurt them.

It ſhould, however, be remembered, that ſuch trees only ſhould be now tranſplanted, whoſe leaves are abſolutely decayed; for with regard to the reſt, they muſt continue ſome time longer before they are removed.

Tranſplant Fruit-Trees.

All thoſe fruit-trees whoſe leaves are now decayed, may alſo be tranſplanted at the latter end of this month. But be ſure to give them ſome water, if the weather be dry.

Tranſplant Stocks to Bud or Graft upon.

During the laſt week in this month, the ſtocks raiſed for budding or grafting different kinds of fruit upon, may be tranſplanted into the places where they are to remain.

Tranſplant Evergreens.

Laurels, Portugal laurels, lauruſtinus, arbutus, phillyreas, and ſeveral other kinds of evergreens, may be tranſplanted about the middle, or towards the latter end, of the month; for they will then take root freely; but remember to give them ſome water ſoon after they are planted.

Propagate Trees and Shrubs by Cuttings.

Gooſeberry and currant-trees may be propagated by cuttings, about the middle or latter end of the month. They will indeed ſucceed, if the cuttings are planted any time between the middle of this month, and the latter end of February; but thoſe planted in this, or the ſucceeding month, generally make the fineſt trees.

Remember that the cuttings, either of the gooſeberry or currant-tree, muſt be taken from the ſame year's ſhoots, and be from ten to fifteen inches in length; they ſhould be planted in a ſhady border.

Honeyſuckles may alſo be propagated from cuttings, about the latter end of the month.

The cuttings ſhould be from ſtrong ſhoots ten or twelve inches in length, and planted in rows about a foot aſunder, and ſix or eight inches apart in the rows. Each cutting muſt be ſet about half way into the earth.

The laurel and Portugal laurel may be propagated by cuttings any time this month; but the cuttings muſt be planted in a ſhady border.

Let the cuttings be taken from the moderate growing ſhoots of the ſame year's growth, remembering to cut off with each ſhoot two or three inches of the laſt year's wood; for this will render the ſucceſs more certain.

When you have provided yourſelf with a ſufficient number of cuttings, take off all the leaves from the bottom half way up the ſhoot; plant them in a ſhady border, putting each cutting as far into the earth as it is ſtripped of its leaves, and give them a little water as ſoon as planted.

Deſtroy Weeds.

Remember to hoe the intervals between the rows of all kinds of trees and ſhrubs, during dry weather, in order to deſtroy all the weeds before the autumn rains begin.

Indeed every part of the nurſery ſhould be kept as free from weeds as poſſible, for they will grow very faſt at this ſeaſon.

The FRUIT-GARDEN.

Plant Strawberries.

Any time this month is a proper ſeaſon to plant ſtrawberries, provided the weather be moiſt; but if the weather be very hot and dry, it will be proper to defer the work till the middle or latter end of the month.

The beds intended for theſe plants ſhould be four feet broad, and four rows ſhould be planted in each bed; allowing an interval or alley of eighteen or twenty inches broad, between the beds, for the convenience of going in to weed, water, and gather the fruit.

Vines.

Look over your vines once more, to ſee that the fruit equally enjoy the benefit of the ſun and air. And wherever you perceive any of the bunches to be too much ſhaded, let ſome of the leaves be taken off; looſening and diſentangling any of the bunches that may be confined, either by the branches or other bunches.

At the ſame time, if you perceive the vines have made any ſhoots ſince they were laſt looked over, let them be rubbed off cloſe; for they are not only uſeleſs, but will alſo draw away part of the nouriſhment from the fruit.

Peaches, Nectarines, &c.

Let your peach, nectarine, and other wall-trees be again examined; and wherever you perceive any of the branches to be looſe, or project from the wall, let them be faſtened up in their proper places. By this means the branches will be in no danger of being broken by the wind, and, at the ſame time, the fruit will enjoy the benefit of the ſun to ripen it.

If you perceive any of the fruit to be too much covered with leaves, let ſome of them be diſplaced. But remember that this is only to be practiſed where they are uncommonly thick, for a ſufficient quantity of leaves is abſolutely neceſſary to the growth and ripening of the fruit.

Deſtroy Waſps, &c.

You muſt ſtill continue your phials of ſugared water, in order to catch the waſps, flies, &c. which will otherwiſe devour the fineſt of your fruit; eſpecially your grapes.

The beſt method indeed of ſecuring the latter, is to put the fineſt and ripeſt bunches into bags made for that purpoſe; theſe will be an effectual ſecurity both againſt inſects and birds.

Your figs will alſo require phials of ſweetened water to be hung up in different parts of the trees; for waſps, hornets, flies, &c. are very fond of this fruit.

Gather Apples and Pears.

Many ſorts of your apples and pears will be fit for gathering about the middle or latter end of this month.

But remember to let this work be done in dry weather, and when the fruit are perfectly dry, otherwiſe they will ſoon rot. They will begin to drop apace from the trees, when they have attained their full maturity; and whenever this happens, let the fruit be gathered.

Make Preparations for Planting.

Towards the latter end of this month, you may begin to prepare the ground where you intend to make new plantations.

If an entire new border for wall-trees be deſigned, let the ground be prepared in the manner mentioned in the introduction to this Kalendar.

The Pleasure or Flower-Garden.

Sow Anemony and Ranunculus Seed.

It is not yet too late to ſow anemony and ranunculus-ſeed, provided it be done at the beginning of the month.

In order to this, let ſome pots, boxes, or tubs, be filled with rich light earth, and the ſurface laid very even. Sow the ſeed, each ſort ſeparate, pretty thick on the ſurface, and cover it with light fine earth about a quarter of an inch thick.

Sow the Seeds of Bulbous-rooted Flowers.

The ſeeds of tulips, hyacinths, crown imperials, fritillarias, and many other bulbous-rooted flowers, may yet be ſown either in beds or boxes; for they will ſucceed in either.

The earth muſt be rich and light, broken very fine, and the ſurface laid very ſmooth and even.

When the earth is thus prepared, let the ſeeds be ſown on the ſurface, each ſort ſeparately, and covered with light ſifted earth about half an inch thick.

Sow Auricula Seed.

You may ſtill ſow the ſeeds of auriculas in large pots or boxes, filled with rich earth, broken very fine, and the ſurface made very ſmooth and even.

The ſeed ſhould be ſown pretty thick on the ſurface, and covered with light rich earth about a quarter of an inch thick.

As ſoon as the ſeeds are ſown, the pots or boxes ſhould be placed out of the reach of the mid-day ſun, till towards the latter end of the month, and then removed into a warmer ſituation.

Propagate Fibrous-rooted Plants.

This is a proper ſeaſon for increaſing roſe campion, ſcarlet lychnis, campanulas, catch-flies, and other fibrous-rooted plants by ſlips.

Theſe plants generally grow in tufts; and where this happens, let the whole be entirely taken up, parted, and ſome of the beſt ſlips planted again in the borders where they are to flower; while the ſmaller ſlips are planted in a nurſery bed to get ſtrength: remember to water them as ſoon as planted.

In the ſame manner you may part the roots of daiſies, polyanthuſes, double chamomile, thrift, gentianella, ſaxifrage, and London pride. Let theſe likewiſe, where they are increaſed to large bunches, be taken up, divided, and then planted in a ſhady border, about five or ſix inches aſunder.

The double rocket, double ragged robin, double batchelor's button, double feverfew, leonurus, bell-flower, and all other fibrous-rooted plants that are paſt flowering, may now be propagated by parting their roots; but it will be better if done about the beginning of the month.

Tranſplant Pionies, and other knot-rooted Plants.

This is a proper ſeaſon for tranſplanting pionies, the different ſorts of flag iris's, monkſhood, fraxinella, and other plants of that kind.

The roots are to be taken up and parted, and then planted again in places where they are to continue.

Tranſplant hardy Shrubs and Trees.

You may begin, about the latter end of this month, to tranſplant moſt kinds of hardy ſhrubs and trees; for they will then ſucceed, and have time ſufficient to take good root before the cold weather comes on. But remember to give them a plentiful watering as ſoon as tranſplanted.

Plant Hyacinth and Tulip Roots.

About the latter end of this month will be a proper time for planting your choice hyacinth and tulip roots.

In

In order to which, let beds be prepared at leaſt a fortnight before the roots are to be planted; eſpecially if you ſtir the earth to the depth of two feet, as is often practiſed by thoſe who are curious in theſe kinds of flowers. But if this be thought too much, let the ground be dug one ſpade deep and one ſhoveling, and, at the ſame time, the ſoil remarkably well broken and divided.

When the ground is thus prepared, let it be parted into beds three feet and a half or four feet broad, laying the earth in a rounding form, higheſt in the middle.

Four or five rows of theſe roots are then to be planted in each bed, allowing nine inches between row and row, and the ſame diſtance between the roots; for nothing is of greater advantage to theſe flowers, than giving them ſufficient room.

It will be neceſſary to bury theſe roots ſo deep in the ground, that their crowns may be at leaſt four or five inches below the ſurface of the bed.

Plant Ranunculuſes and Anemonies.

About the middle or latter end of this month it will alſo be time to prepare the ground for planting the fineſt ſorts of your anemonies and ranunculuſes.

If you intend theſe roots in beds by themſelves, let the beds be about three feet and a half or four feet broad, laying them ſomewhat rounding, as was mentioned above with regard to thoſe intended for hyacinths and tulips.

When the beds are ready, let the roots be planted in them at ſix inches every way from one another; and about two or three inches deep.

The above diſtances are conſiderably greater than what is commonly allowed for theſe flowers; but room is of the utmoſt advantage to them; for the flowers will be much larger, and ſhew themſelves to much greater advantage, than when they are placed cloſer together. At the ſame time they will produce much larger off-ſets, and conſequently increaſe much faſter.

Plant Box.

About the middle of this month is a very proper ſeaſon for beginning to plant box, where new edgings are wanted, for it will then take root freely; but remember to give the box a plentiful watering as ſoon as the edgings are planted.

This is alſo a very proper time for repairing any box edgings formerly planted; or removing them where they have grown thick and clumſy. In order to which, the edging ſhould be wholly taken up, the roots parted, and a proper quantity of the box be ſlipped, trimmed, and immediately planted down again in a cloſe but thin edging.

In a month after planting the box will be well rooted, and the edgings will appear neat during the whole winter.

Tranſplant Carnations, and other Perennial Plants.

Towards the latter end of this month, ſome of your ſtrongeſt carnations, pinks, ſweet-williams, ſeedling wall-flowers, ſtock-july flowers, columbines, and other perennial plants, ſown in June, or beginning of ſummer, may be tranſplanted into the borders.

But it will be proper to take the advantage of dripping weather for tranſplanting them at this ſeaſon.

At the ſame time many of thoſe which were pricked out from the ſeed-bed into nurſery beds, two or three months ago, may now be ſafely taken up with balls of earth about their roots, and planted where they are intended to remain. By this practice the plants will hardly feel their removal. But do not forget to give each plant as ſoon as removed a moderate watering; for this will at once nouriſh the plants, and cloſe the earth about their roots.

Management of Carnation Layers.

Your carnation layers muſt now be taken care of. If any of them ſtill remain on the old plants, let them be tranſplanted ſome time before the middle of the month, that they may have time to take good root before the winter.

You may plant the choiceſt kinds of theſe layers in ſmall pots, in order to their being more eaſily protected during the ſevere weather in the winter. But the common ſorts may be planted in nurſery-beds in a warm ſituation; and ſome of the ſtrongeſt layers may be planted out at once into the borders where they are intended to flower.

With regard to thoſe layers that were planted in pots or beds during the former month, let them be watered now and then, if the weather proves dry; and be ſure to keep them entirely free from weeds.

Management of Auricula Plants in Pots.

All your auricula plants in pots will now require attention, particularly thoſe that were ſhifted laſt month. If the weather prove very dry, they muſt be moderately watered now and then: on the contrary, if a great deal of rain falls, they muſt be defended from it; for too much wet will rot their roots.

Let therefore the pots containing your choicer plants be placed together in a bed arched over with hoops; and when the weather is exceſſively wet, let thick mats or canvas be drawn over the hoops to defend the plants. By this method the plants will be much better protected from wet than by that commonly made uſe of, namely, to lay the pots down on one ſide. But if a convenience of this kind cannot be had, the pots muſt be laid down on one ſide, that the plants may not receive too much moiſture, which would deſtroy them.

Clear away decayed Flower Stalks.

Remember to go round your borders frequently, cutting down the ſtems of ſuch plants as are paſt flowering: theſe ſhould never be ſuffered to ſtand long after their bloom is over, for dead ſtems have a very unſightly appearance among plants, whether growing or in bloom.

Trim flowering Plants.

Examine frequently your plants in general, and cut off all ſtraggling or irregular branches, together with thoſe that are weak and dangling, and all dead or damaged leaves.

At the ſame time tye up to ſtakes ſuch plants as have been thrown down by the winds or too much wet. This will give an air of neatneſs to the whole, and greatly improve the elegant appearance of your flowering plants.

Cut Box Edgings.

If you omitted to clip your box edgings during the two preceding months, let it be done now, and the

sooner the better, that the box may have time to recover, before the winter comes on.

Clip Hedges.

All your hedges that ſtill remain unclipped, muſt now be finiſhed; nor ſhould it be deferred beyond the middle of the month, for the ſhoots will ſoon acquire too great a degree of hardneſs.

Remember to keep your ſheers in the beſt order; for otherwiſe the work will be tedious, and badly performed.

Let the ſides of the hedges of all ſorts be trimmed as ſtraight as poſſible, and in ſuch a manner, that the hedge may run ſomewhat tapering from the bottom to the top; for the former ſhould always be broader than the latter. With regard to the top, the utmoſt care ſhould be taken to cut it very ſtraight and even.

Clean Borders.

Take particular care to keep your borders, eſpecially thoſe near the principal walks, always very neat and clean. Neither weeds, dead leaves, nor any other litter ſhould ever appear on thoſe borders.

Mow Graſs Walks and Lawns.

Let your graſs walks and lawns be mowed frequently, otherwiſe they will have a diſagreeable appearance; nor will it hardly be poſſible to mow the graſs with any degree of truth, if it be once ſuffered to grow very rank and rough.

Remember alſo to keep the edges of all the graſs, bordering upon gravel walks, very cloſe and neat. Theſe edges ſhould be cut once a fortnight during the ſummer ſeaſon.

Roll Gravel Walks.

It will be neceſſary, if you would have your gravel walks look well, to roll them at leaſt twice a week. Nor ſhould you ſuffer any weeds or other litter to be ſeen upon them.

OCTOBER.

Work to be done in the KITCHEN-GARDEN.

Cauliflower Plants.

THOSE cauliflower plants which were planted laſt month under frames, ſhould about the latter end of this month, be planted out under hand or bell-glaſſes; but unleſs the weather ſhould prove very wet and cold, they need not be covered at all with the glaſſes; and even in the day-time of heavy rains, let the plants have air by tilting up the glaſſes.

During the laſt week of this month, ſome of your beſt cauliflower plants ſhould be removed into the place where they are to remain. But as they are to be covered with hand or bell glaſſes, two or three of the plants are to be put under each glaſs.

The ground for theſe plants ſhould be rich and light, ſituated in a warm part of the garden, where water is not apt to ſtand in winter.

Before the ground is dug, let ſome good rotten dung be ſpread upon the ſurface, and then dug ſpade deep, taking care to break the clods very well, and to bury the dung equally.

When this is done, let the ground be divided into beds three feet wide, allowing a foot and a half between the beds for the conveniency of putting on, raiſing, or taking off the glaſſes.

The beds being thus laid out, ſtretch your line along the middle of each bed from one end to the other, and at every three feet put in two or three plants, within four or five inches of each other, and cloſe the earth well about their roots and ſtems, giving them a moderate watering to ſettle the earth about their roots.

As ſoon as the planting is finiſhed, bring your hand or bell-glaſſes, and place one of them over each clump of plants every night, removing them in the morning while the weather continues mild and dry.

But when the weather is extremely wet, the glaſſes muſt not be taken entirely off; they muſt be only raiſed two or three inches on the warmeſt ſide, and ſupported in that poſition with props, to admit air to the plants: in froſty weather they muſt be kept cloſe.

If you have not hand or bell-glaſſes, you may remove ſome of your plants into a warm border, where they will, if the winter be mild, produce tolerable heads in the ſpring.

Cabbage Plants.

A few of your early cabbage plants may be removed into the beds where they are to cabbage next ſummer, about the middle or latter end of the month.

In order to this, let ſome good rotten dung be ſpread over the ſurface, and the ground dug one ſpade deep, remembering to bury the dung properly in the bottom of the trench.

When the ground is ready, let the plants be ſet in rows two feet aſunder, and the ſame diſtance apart in the rows.

As it often happens that cabbage plants removed early into an open expoſure, are, in ſevere winters, killed by the froſt, it will be prudent to let ſome of the early cabbage plants remain in nurſery beds made in a warm ſituation, till January or February, that you may have plants to ſupply any defects in the former, or even to form new plantations.

Let therefore all your cabbage plants that ſtill remain in their ſeed-beds, be now removed into nurſery-beds at the beginning of this month, that they may have time to get ſtrength before the ſevere weather begins. And remember to let the beds be made in a warm ſituation, and to ſet the plants about five or ſix inches aſunder.

Broccoli.

Let the ground between and about the broccoli plants which were ſet late be looſened with a hoe, and ſome of the earth drawn up about their ſtems; for this will be of the utmoſt advantage to them, provided it be done early in the month.

Beans.

Beans.

A few mazagan beans may be planted any time this month for an early crop in the ſucceeding ſummer.

But remember to plant them in a warm border under a ſouth wall or other fence, in rows two feet and a half aſunder, dropping the beans two or three inches apart in the rows.

Many gardeners, in planting early beans, chooſe firſt to ſow the beans pretty thick in a bed of rich earth, and tranſplant them into the borders when they are come up to a ſufficient height. The method is this:

Let a bed of good rich earth, about four feet broad, ſituated in a warm corner of the garden, be well dug. Then draw off the ſurface of the earth to the depth of an inch and a half, or two inches, from every part of the bed equally. This being done, ſcatter the beans about an inch aſunder, and immediately cover them with the earth drawn off the bed.

When the beans are come up, and grown about two inches high, they ſhould be tranſplanted in mild weather into warm borders, in rows two feet and a half aſunder, and two or three inches apart in the rows. Remember to cloſe the earth well about their roots, and there will be no danger of their growing freely.

Experience has ſhewn, that beans tranſplanted in the above manner, will come a week or ten days ſooner than thoſe planted in the place where they are to remain; provided both are ſet the ſame day.

At the ſame time there will be leſs danger of their being injured by the froſt, as they may, from being crowded together in the ſeed-bed, be more eaſily protected by covering them when the weather is very ſevere.

Peas.

About the firſt or ſecond week in this month, a few peas ſhould be ſown for an early crop. The earlieſt hotſpur is the moſt proper ſort to be ſown at this ſeaſon; but remember to make choice of ſuch ſeeds as are plump and ſound.

They ſhould be ſown in a warm border under a ſouth wall, in drills two feet aſunder, and the peas placed pretty cloſe together in the drills, but as regular as poſſible, and covered immediately with earth an inch and a half or two inches deep.

Lettuces.

Thoſe lettuces which were ſown about the middle of September, in order to be covered with frames or hand-glaſſes, ſhould be removed, about the middle of this month, into the places where they are to remain.

In order to this, a ſpot of light rich earth, in a warm ſituation, and fully expoſed to the mid-day ſun, ſhould be choſen, and a bed proportioned to the ſize of a cucumber or melon frame marked out; the ſurface laid ſomewhat ſloping to the ſun, and raked very ſmooth and even.

When the bed is thus prepared, let the lettuces be planted, not too deep in the earth, about two inches diſtant every way. Let them have a little water as ſoon as planted, and let the ſurface between the plants be made perfectly ſmooth.

The plants being thus ſet in the bed, put on the frame, and, when the weather is wet and froſty, cover it with the lights. By this precaution there will be no doubt of theſe plants ſurviving the cold of winter, notwithſtanding thoſe which were planted in borders are deſtroyed.

About the middle of this month will be alſo a very proper time to tranſplant thoſe lettuces which were ſown about the latter end of Auguſt or the beginning of September, into the places where they are to remain.

But you muſt remember to chuſe a warm border for their reception; and then, if the weather prove mild, they will cabbage early in the ſpring.

Spinnage.

Remember to keep your winter ſpinnage perfectly clean from weeds; for if the latter are ſuffered to grow at this ſeaſon of the year, they will ſoon overrun, and totally deſtroy the plants.

If you neglected to thin your ſpinnage laſt month, let it be done at the beginning of this; remembering to clear away the weaker, and to leave the ſtronger plants at the diſtance of four or five inches from one another.

Endive.

You muſt remember, provided the weather be dry, to tye up ſome endive plants every week for blanching.

In order to this, let ſuch plants be choſen as are quite or nearly full grown; to let the leaves be regularly and cloſely gathered up in the hand, and tyed neatly together with a piece of ſtrong baſs.

At the ſame time let the earth be drawn up round each plant almoſt to the tops of the leaves; for this will at once promote the blanching, and render the plants exceeding white and tender.

Earth up Celery.

As your celery plants advance in height they muſt be duly earthed up, that they may be thoroughly branched before they are attacked by ſevere froſts.

Let therefore every advantage of dry weather be taken, in order to earth them up to a proper height. At the ſame time remember to break the clods of the earth very well, and to lay it up to the plants, without breaking their leaves or burying their hearts.

Earth up Cardoons.

Remember to earth up your cardoons when both the weather and the leaves, of the plants are dry, in the manner mentioned the foregoing month.

Sow Carrot Seed.

About the laſt week in this month, a little carrot ſeed ſhould be ſown on a warm border; as it is very probable a few of the plants, at leaſt, will ſurvive the froſt, and conſequently produce young carrots very early in the ſpring.

Sow Raddiſh Seed.

A little raddiſh ſeed ſhould alſo be ſown about the middle of the month, in a warm border; for if the weather be any thing mild, the plants will be fit for drawing early in the ſpring. Let the ſeed be ſown pretty thick, and raked in with an even hand.

Sow ſmall Sallad Herbs.

A ſmall quantity of the ſeeds of muſtard, creſſes, raddiſh, rape, and lettuce, ſhould be ſown every week; but that ſown about the latter end of the month ſhould be defended by a frame and glaſſes.

In order to this, let a bed of light rich earth, in a warm ſituation fronting the ſouth, be dug, and proportioned to one of the ſhalloweſt garden frames. Let the earth be broken very fine, and laid a little ſloping towards the ſouth.

When the ſurface is raked very even, let ſhallow drills be drawn from the back to the front of the frame, about two or three inches aſunder. In theſe drills let the ſeed be ſown pretty thick, and covered with earth about a quarter of an inch deep.

The glaſſes muſt be put on every night, and continued alſo in the day-time, when the weather is very cold or wet.

Dreſs Aſparagus Beds.

The ſtalks of your aſparagus muſt be cut down, and the beds properly dreſſed ſome time this month.

Remember to cut down the ſtalks or haulm within two or three inches, at leaſt, of the ſurface of the beds, and immediately to carry it off the ground.

When this is done, cut up all the weeds with a ſharp hoe, and draw them off into the alleys, which are to be marked out with a line and ſpade, about eighteen or twenty inches wide.

The beds being thus cleared, let the alleys be dug one ſpade deep, ſpreading the earth, or at leaſt the greater part of it, neatly over the beds, obſerving, as you advance in digging, to bury the weeds taken off the beds in the bottom of the trench, and to cover them a proper depth with earth.

If you intend to manure your aſparagus-beds, this is alſo the proper ſeaſon to do it; but the dung, which muſt be applied before the alleys are dug, ſhould be very good, and very rotten. None is more proper than the dung of old cucumber and melon beds. This muſt be ſpread over the ſurface, as the haulm and weeds are cleared away: let it be well broken, and laid of an equal thickneſs on every part of the beds. When this is done, let the alleys be dug as above directed, and a proper quantity of the earth ſpread upon the dung.

You may plant a row of cabbages or coleworts in each alley, five or ſix inches apart in the row. And theſe will generally ſurvive very ſevere froſts, when all thoſe planted in an open or level ſpot will be deſtroyed.

Clear the Beds of Aromatic Plants.

Your beds of ſage, ſavory, thyme, hyſſop, mint, baum, tarragon, tanſey, ſorrel, &c. muſt now be dreſſed in the following manner:

Let all the ſtalks, or decayed flower-ſtems, be cut cloſe to the heads of the plants, or the ſurface of the ground; the beds well cleared from weeds and other litter, and the whole carried off the ground.

When this is done, let the earth be dug lightly between ſuch of the plants as will bear it, either with a ſpade or trowel. At the ſame time, let the alleys be dug, and a little of the earth ſpread upon the beds. If a little rotten dung had been ſcattered over the beds before they had been dug, it would have been of great advantage to the plants.

The beds of mint, and pepper-mint, will not admit of digging; but let them be well cleared from weeds, a little rotten dung ſpread over the ſurface, and ſome of the earth from the alleys thrown over the dung. By this means the roots will, in ſome meaſure, be protected from the froſt; and the rain, by waſhing down the ſalts of the dung and earth, will greatly enrich the beds, and ſtrengthen the plants.

Dung and Trench Ground.

The parts of the kitchen-garden now unoccupied ſhould be dunged and trenched, that it may receive every poſſible advantage from the ſun and air. By this means the ſoil will be greatly enriched, and conſequently produce much larger crops in the ſpring, than it would if ſuffered to have lain neglected till it was wanted.

The Nursery.

Sow Haws, Holly Berries, &c.

This is the ſeaſon for ſowing haws, holly, hips, and yew-berries.

In order to which, let beds of three feet and a half, or four feet wide, be prepared; the berries of each ſort ſeparately ſown on the ſurface, and covered near an inch deep with earth.

Many bury their haws and holly-berries a whole year in the earth, before they ſow them, for they ſeldom come up before the ſpring twelvemonth after they are ſown. The method is this:

They mark out, in ſome part of the nurſery, where the ground is firm and dry, a trench about two feet wide, dig it twelve inches deep, and make the bottom very even and level. In this trench they lay the berries of an equal thickneſs, and cover them with earth ſix inches deep, at leaſt.

In this manner they are ſuffered to lie a twelvemonth, when they are taken up, and ſown in beds as above directed.

Sow Acorns.

About the latter end of this month your acorns muſt be ſown, for, if kept much longer out of the ground, they will begin to ſprout.

They ſhould be ſown in beds about four feet wide, and covered an inch deep with earth.

Sow Plum-Stones.

This is a very proper ſeaſon for ſowing plum-ſtones, to raiſe a ſupply of ſtocks for the purpoſe of budding and grafting.

In order to this, let beds about four feet broad be dug, the ſtones ſpread, not too thick, as equally as poſſible on the ſurface, and covered a full inch deep with earth.

If you ſcatter ſome dry ſhort litter over the ſurface of the beds as ſoon as they are planted, it will prove of great ſervice.

Some preſerve theſe ſtones till about the middle of February, and then plant them in beds as above directed. The method they take to preſerve the ſtones is this:

They procure a ſtrong cloſe box or tub, and cover the bottom three inches deep with ſand. When this is done, they ſcatter on it a parcel of the ſtones, covering them two inches deep with ſand; upon this covering they ſcatter another parcel of the ſtones, covering them in the ſame manner, and ſo proceed till the tub or box is

is full. By this artifice the vegetative faculty of the ſtones is preſerved, and they may be ſown any time in February, when the weather is favourable.

Sow Beech-maſt, &c.

This is the beſt ſeaſon in the whole year for ſowing beech-maſt, and maple ſeed.

Let therefore a bed four feet broad be prepared for each of theſe ſeeds; the earth well broken, and the ſurface laid very ſmooth.

When this is done, let the ſeeds be ſown pretty thick on the ſurface, and covered with earth about an inch deep.

Propagate Trees and Shrubs by Layers.

About the middle of this month, you may begin to propagate the hardier kind of foreſt-trees, and flowering-ſhrubs, by layers. The method is this:

Dig the ground round the tree or ſhrub you intend to propagate. When this is done, bring the branches down, lay them in the earth, and faſten them down with forked or hooked ſticks. Then cover the body of the ſhoots three or four inches deep with earth, leaving the tops three or four inches above the ground.

Limes, elms, and other foreſt-trees, will ſucceed extremely well by this method; but it will be neceſſary to cut down the tree, from which the layers are intended to be taken, near the ground, that it may produce ſhoots or branches at a height proper for this operation.

Propagate Trees and Shrubs by Cuttings.

Many of the hardy kinds of trees and ſhrubs may be propagated by cuttings; and this is a very proper ſeaſon for doing it.

Honey-ſuckles, gooſberry and currant-trees are better raiſed by cuttings than by any other method. The manner of performing this operation has been fully deſcribed in the work of the nurſery for laſt month.

Tranſplant Layers.

Thoſe layers which were laid down laſt year muſt now be taken off, and planted in an open ſpot of ground, in rows eighteen inches aſunder, and twelve inches apart in the rows.

Tranſplant hardy Trees and Shrubs.

You may, any time this month, tranſplant all ſorts of hardy trees and ſhrubs; and by next ſummer they will have fixed themſelves firmly. This will be of great advantage; for they will require very little trouble in watering.

Tranſplant Stocks to Bud and Graft upon.

This is a very proper ſeaſon for tranſplanting all kinds of ſtocks intended for budding or grafting the different ſorts of fruit upon.

They ſhould be planted in rows two feet and a half aſunder, and twelve or fifteen inches be allowed between the ſtocks in each row.

Tranſplant Laurels.

Laurels, Portugal laurels, laruſtinus, and other evergreens of that kind, may be tranſplanted with ſafety at the beginning of the month.

The FRUIT-GARDEN.

Prune and Nail Peach, Apricot, and Nectarine Trees.

As ſoon as the leaves of your peach, apricot, and nectarine-trees, are dropped, which will happen about the latter end of this month, you may begin to prune and nail them.

Remember to unnail the greater part of the ſmall branches, before you begin to prune; becauſe you will have room to uſe your knife with greater facility; and, at the ſame time, may examine with more convenience the ſeveral ſhoots, and conſequently be better able to judge which are proper to be taken off, and which to remain.

You muſt be careful to leave at equal and regular diſtances, and in every part of the tree, a proper ſupply of the laſt ſummer's ſhoots, that every part of the wall, from the bottom to the top of the tree, may be regularly furniſhed with them; for theſe, and theſe only, are the ſhoots that will bear the fruit next ſeaſon.

At the ſame time, remember to cut out all the old wood, as it becomes uſeleſs; we mean ſuch branches as advance a great way, and are not furniſhed with young wood.

But though a ſufficient number of the young ſhoots are to be left, yet they muſt not be crowded, or left too cloſe together. Let them therefore be carefully examined, and where you perceive they ſtand too thick, let ſome of them be taken away. In doing this, remember to leave the moſt promiſing and beſt placed ſhoots for the purpoſe of bearing, and to leave them at due and regular diſtances from one another; five or ſix inches will be a proper interval between them, if the tree be in good health. Thoſe which you take away muſt be cut off cloſe.

When you have taken away all the uſeleſs ſhoots, you muſt ſhorten thoſe you intend to preſerve; for by this means they will next ſummer produce, beſides their fruit, a proper ſupply of bearing ſhoots for the year after.

But, in doing this, remember to ſhorten every one in proportion to its growth, and original length: for inſtance, a ſhoot of about twelve inches muſt be reduced to about eight inches, one of fifteen or ſixteen to ten, and a ſhoot of twenty to fourteen; and ſo on in proportion to their different lengths. In a word, you ſhould cut away about one third of the length of every ſhoot.

A difference muſt, however, be made with regard to thoſe nectarine and apricot-trees which produce very ſtrong and vigorous ſhoots; for theſe muſt be left about five or ſix inches aſunder, and not more than one fourth of their original length muſt be cut off; indeed ſome of the moſt vigorous ſhoots ſhould be but very little ſhortened, and others not at all. For the more wood you cut out of a vigorous tree, and the more the ſhoots are ſhortened, the more vigorouſly will the tree ſhoot. This, therefore, is the only method of pruning a vigorous ſhooting tree, in order to its producing ſuch moderate ſhoots as are neceſſary for their bearing fruit.

If the above obſervations be well underſtood, the gardener will be at no loſs in pruning apricot, peach, and nectarine-trees, in proportion to their different growths.

But

But it will be neceſſary to obſerve, that where any of the ſhoots left to bear have produced any ſmall ſhoots from their ſides, they muſt be cut off cloſe to the principal ſhoot; for theſe will be entirely uſeleſs; they will produce neither good wood, nor good fruit.

In ſhortening the bearing ſhoots, you ſhould remember to cut them off at a leaf bud, or, as ſome call it, a double bud, if poſſible. A leaf, or double bud, is where two buds appear upon the ſame eye. Every one of theſe eyes will generally produce a good ſhoot next year; it is therefore neceſſary, in ſhortening the ſhoots, to cut them at or near ſuch an eye, in order that each may produce a good ſhoot next year for its leader; for where there is a fair leading ſhoot produced at or near the extremity of a bearing branch, ſuch a ſhoot will generally yield fair and well-taſted fruit.

With regard to the apricot-tree, in particular, it ſhould be obſerved, that there are often on the two years old branches ſhort ſhoots, or natural ſpurs, about an inch or two in length, and, frequently, on each of theſe ſpurs ſeveral bloſſom buds. Some cut theſe ſpurs entirely away; but this is bad practice; for they generally produce handſome and well-taſted fruit. But, at the ſame time, ſuch only of theſe ſpurs which are well placed, and promiſe, by their bloſſom-buds, to bear fruit, ſhould be ſpared; ſuch as advance conſiderably in a foreright direction, together with ſuch as are deſtitute of bloſſom-buds, ſhould be cut off cloſe to the branch.

Remember, as ſoon as you have finiſhed pruning one tree, to nail it cloſe to the wall in a proper manner, before you begin the next; and not leave it, as many do, till all the trees on the wall are pruned. Some, indeed, direct them to be left unnailed till March; but by this method many of the branches will be injured by the winds, and the bloſſom-buds ſo much ſwelled by the time of nailing them, that many of them will unavoidably be diſplaced in the operation.

You ſhould obſerve great exactneſs in nailing your trees: the branches muſt not any where be nailed acroſs one another; but every branch laid in entirely clear of the reſt, and about four, five, or ſix inches diſtant, according to the condition of the tree. At the ſame time, let all the branches be laid perfectly ſtraight, and cloſe to the wall.

Tranſplant Fruit-Trees.

Moſt ſort of fruit-trees may be ſafely tranſplanted about the latter end of this month.

In the introduction to this Kalendar, we have given full directions for making borders, and mentioned the diſtances that are neceſſary between the trees of different ſorts of fruit, and therefore it will be needleſs to ſay any thing on that ſubject here.

Propagate Gooſeberry and Currant-Trees by Cuttings.

This is a very proper ſeaſon for propagating gooſeberry and currant-trees by cuttings; and it ſhould be remembered, that the trees raiſed from cuttings always produce larger and better taſted fruit, than thoſe which are raiſed from ſuckers.

Theſe cuttings muſt be ſhoots of the laſt ſummer's growth, taken from healthy trees, and ſuch as are remarkable for bearing the fineſt fruit of their kind.

When a proper number of theſe ſhoots are provided, let them be ſhortened to about ten, twelve, or fifteen inches in length; and planted in a ſhady border, in rows acroſs the border, ten or twelve inches aſunder. Each cutting muſt be ſet near half its length into the earth.

Prune Gooſeberry and Currant-Trees.

About the latter end of this month, your gooſeberry and currant-trees may be pruned. In doing which, obſerve to keep their branches thin, and at regular diſtances from one another. The heart of the trees alſo muſt be kept open and free from wood, and the branches no where ſuffered to croſs one another.

At the ſame time, remember to take away all ſuckers from the roots, and to train up each tree with a ſingle ſtem.

It is natural for theſe trees to produce numbers of young ſhoots every ſummer, many of which ſhould be now taken away; but be ſure to leave at proper diſtances, ſome of the beſt placed, and moſt regular grown ſhoots, for a ſucceſſion of young bearing wood, to ſupply the place of ſuch branches as are paſt bearing good fruit; remembering, at the ſame time, to cut ſhorter, or remove entirely, ſome of the older branches, in order to make room for thoſe which are young, and promiſe to bear better fruit.

You ſhould alſo remember, in ſhortening the laſt ſummer's ſhoots, not to cut off more than one third of their length; and where the ſhoot is very vigorous, one fourth will be ſufficient; for if they are ſhortened much more than this, their vigour will be ſo greatly increaſed, that they will next year fill the tree with ſo many uſeleſs ſhoots as will prove prejudicial to the fruit.

Tranſplant Gooſeberry and Currant-Trees.

About the middle, or towards the latter end, of this month, will be a proper ſeaſon for tranſplanting gooſeberry and currant-trees.

If theſe ſhrubs are intended to be ſet in a ſpot by themſelves, let them be planted in rows eight feet aſunder; and let ſix feet, at leaſt, be allowed between plant and plant in the rows. This will give room to dig and hoe the ground between the ſhrubs; and the berries will grow very large, and ripen properly.

But if they are intended to be ſet in ſingle rows round the quarters of the kitchen garden, they ſhould be planted eight or nine feet diſtant from one another.

Plant Strawberries.

Where new plantations of ſtrawberries are wanting, they may be made any time this month, but the ſooner the better.

In order to this, let ſome of the beſt rotten dung be ſpread over the ſurface of the ground where you intend to plant your ſtrawberries, and then neatly dug, remembering to bury your dung in a proper manner.

When the piece is thus prepared, let it be divided into beds four feet broad, leaving an interval of eighteen inches for an alley between the beds, and rake the ſurface very ſmooth.

The beds being thus in readineſs, chuſe a parcel of the ſtrongeſt plants produced laſt ſummer, and take them up with good roots. Cut off all the runners, pull

pull off all the dead leaves, trim the roots, and plant them in four rows lengthways of the bed. Conſequently the rows will be one foot aſunder; and the ſame diſtance ſhould be allowed between each plant in the rows.

Remember to cloſe the earth well about every plant, and to give e..n of them a little water as ſoon as they are ſet.

Dreſs Strawberry Beds.

It will be neceſſary to give your ſtrawberry beds their winter's dreſſing ſome time this month; but remember to chooſe a dry day for it. The manner is this:

Clear away all the runners or ſtrings cloſe to the head of the plants; clean the beds from weeds, and let all the litter be carried away.

When this is done, let the earth in every bed, where there is room, be looſened with a ſmall ſpade, trowel, or hoe, taking care not to diſturb the roots. Then mark out with your line the alleys of their proper width, and dig them immediately, ſpreading ſome of the earth c.refully over the beds; taking particular care to lay it neatly between, and cloſe about every plan.

The plants ſhould never be ſuffered to ſpread over the whole ſurface of the bed; they ſhould be kept, as it were, in ſingle bunches or heads. And by purſuing this method you will every year, when the ſeaſon is kind, have a great quantity of large and well taſted fruit.

Plant Raſpberries.

This is a very proper ſeaſon for making new plantations of raſpberries; but the ſpot intended to be planted muſt be in an open ſituation, and the ground good.

The plants muſt alſo be well furniſhed with roots, or they will not ſucceed: let therefore ſuch only be choſen.

Being furniſhed with a proper number of ſuch plants, let the ſhoots be ſhortened a little, and only one ſtrong ſhoot left on each root. The extremities of the roots alſo muſt be trimmed; and then planted in rows four feet aſunder, and the plants ſet three feet apart in the rows.

Prune Raſpberry Plants.

Experience has ſufficiently ſhewn that three only of the laſt year's ſhoots ſhould be left upon each root for bearing fruit the next year; theſe muſt therefore be allowed room; and, in order to this, all above that number on each root muſt be now removed. In doing this let them be cut off cloſe to the ſurface of the ground; cutting away at the ſame time all the old wood, together with all the ſtraggling branches between the rows.

When this is done, let each of the branches left to bear fruit the ſucceeding year be ſhortened, cutting off about one third or one fourth, in proportion as the ſhoot is leſs or more vigorous, of its original length.

When this is done, and all the cuttings, &c. cleared away, let the ground in the intervals and between the roots be dug, clearing away all the ſtraggling roots between the rows, together with thoſe that do not belong to the ſtanding plants.

Gather Winter Apples and Pears.

This is generally the ſeaſon for gathering winter apples and pears. But they will be ripe at different times; ſome at the beginning, ſome about the middle, and others not till the latter end of the month.

In order to know whether the fruit are proper to be pulled, try ſeveral of them in different parts of the tree, by turning them gently upwards: if they quit the tree eaſily, it is time to gather them; if not, they muſt remain ſome time longer.

You ſhould not, however, let any of your fine eating pears hang on the trees after the middle of the month, eſpecially if the nights are inclinable to be froſty; for if they are once touched with the froſt, many of them will rot before they are fit for the table, notwithſtanding all the care that can afterwards be taken of them.

Nor muſt any kinds of apples or pears be ſuffered to hang longer on the trees than the latter end of the month; for after that time they will get no good by being abroad.

But whenever you gather any of your keeping fruit, let a dry day be choſen; and before you begin to gather, let both the fruit and leaves be thoroughly dry. Between eleven and twelve is generally the beſt time to begin; nor ſhould the work be continued after three or four in the afternoon.

Take care to pull your fruit one by one, and to lay them gently in a baſket; for if they are bruiſed by any means, they will ſoon be ſpoiled.

Carry the fruit as ſoon as they are gathered into the fruitery, or other dry place, laying them carefully in heaps, each ſort by itſelf.

In theſe heaps they muſt be ſuffered to lie a fortnight to ſweat; which will at once improve their flavour, and make them keep the better.

After ſweating in this manner, let them be wiped one by one, and laid up where they are to remain. Remember, in ſevere froſty weather, to cover them with clean new ſtraw.

The Pleasure or Flower-Garden.

Management of Carnation Layers.

You muſt during the laſt week in this month remove your carnation layers, planted into ſmall pots during the two laſt months, into places where they can be readily defended in bad weather; a common garden frame will be very proper for this purpoſe; and if the earth be light and dry, let the pots be plunged into it up to the rims.

In this frame let the pots remain during the winter, obſerving when the weather is froſty or very wet, to cover them with the glaſſes; and when the cold is very ſevere, to throw mats over the glaſſes. But let them conſtantly enjoy the benefit of the open air, when the weather is dry and mild.

If you have not the convenience of a frame, let the pots be plunged in a bed of dry compoſt, arched over with hoops, and covered over with the mats or canvas in bad weather.

Management of Auricula Plants.

It is neceſſary to defend your auricula plants in pots from froſt and heavy rains. In order to which, many perſons think it ſufficient to lay the pots down on one ſide; but this is a very poor expedient, as ſeveral methods more effectual may be eaſily contrived.

A garden frame will anſwer the purpoſe with very little trouble, as the plants may be defended in bad

weather by putting on the glaſſes. But if a frame cannot be ſpared, let the pots be placed cloſe together under a warm wall, and arched over with hoops, that when the weather is very wet or froſty, canvas or mats may be thrown over them.

But whatever method be taken for the ſecurity of theſe choice flowers, let all the dead leaves be taken from the plants, and the earth near the ſurface looſened.

Plant Tulips and Hyacinths.

It is not yet too late to plant tulips and hyacinths, but it ſhould be done ſome time this month.

Remember to dig the ſpot where you intend to plant them very well, and to lay the ſurface of the beds rounding, or in a convex form, in order to throw off the wet. The beds ſhould be four feet broad.

Five rows of roots ſhould be planted in a bed, about nine inches apart, and four or five inches deep. Remember to chuſe a dry day for ſetting theſe roots.

If you intend to ſet any of theſe roots in the borders among other flowers, let them be planted in clumps or patches, rather than in ſingle rows. In order to this, let a ſmall circle ſeven or eight inches diameter be drawn in the border, with your finger, and ſet one root in the center, and three or four round the circumference; and in that manner plant a clump at about every two or three yards diſtance. The flowers planted in this manner will make a much more pleaſing appearance in the flowering ſeaſon than they would, had they been planted in a ſingle row.

But the choiceſt flowers ſhould always be planted in beds by themſelves, becauſe they may be more eaſily ſheltered from too much rain, and alſo ſhaded from the ſcorching rays of the ſun, both of which would greatly impair their beauty.

Plant Ranunculuſſes and Anemonies.

This is alſo a good ſeaſon for planting the roots of ranunculuſſes and anemonies; but remember to plant the choicer ſorts in beds by themſelves.

In order to which let the ground be well dug, and divided into beds four feet broad. In each of theſe beds let five rows of the roots be planted ſix inches from one another, and about two inches and a half or three inches deep. By allowing them this diſtance, which is greater than common, the roots will blow much ſtronger, and the flowers will appear to much greater advantage.

Remember to cover the beds where your fineſt are ſet, with peas-haulm, or other dry litter, in very ſevere froſts.

With regard to the common ſorts of ranunculuſſes and anemonies, they may be planted in clumps in the borders, where they will make a very agreeable appearance in the ſpring among other flowers.

Plant Crocuſſes and Snow Drops.

Let the crocus and ſnow-drop roots which were taken out of the ground in the ſummer be now planted in the borders, either in rows or in clumps. If in the former, the roots ſhould be ſet ſix inches apart.

But they will make a much finer appearance if planted in clumps or patches. In order to which mark out a ſmall circle about five or ſix inches diameter, and plant one root in the center, and four or five round the edge or circumference; two feet farther mark out another circle, and plant it in the ſame manner; continuing the ſame method to the end of the border.

These roots ſhould never be planted above three inches deep; two and a half ſtill, in general, be ſufficient.

Plant Narciſſus's, Jonquils, &c.

Your narciſſus's, jonquils, bulbous and Perſian iris's, fritillarias, and other bulbous roots of that kind, which were taken up when their leaves decayed in ſummer, ſhould now be planted.

If they are intended to be ſet ſeparate in beds, let them be planted in rows eight or nine inches aſunder every way. But if they are to be planted in the common borders, let them be planted three or four together in a ſmall circle, allowing five or ſix feet between each circle or clump.

Plant Crown Imperials, Martagons, &c.

This is likewiſe a proper ſeaſon for planting your crown imperials, martagons, orange lillies, and other bulbous roots of that kind, which were taken out of the ground in the ſummer.

They ſhould be planted in rows in the middle of a bed or border, each ſort at ten or twelve feet diſtance from one another, intermixing them as you proceed; each root ſhould be about three feet diſtance from the next.

Plant Hardy Flowering Shrubs.

Roſes, honey-ſuckles, gilder-roſes, lilacs, laburnums, ſyringas, althæa frutex, jaſmines, privets, double bramble, flowering raſpberry, double bloſſom cherry, bladder and ſcorpion ſena, double flowering peach, almonds, mezereons, cornelian cherry, double hawthorn, ſcarlet horſe-cheſnut, ſhrub cinqueſoil, ſumach, rock-roſe, cytiſuſes, acacia, and other hardy flowering ſhrubs may be now tranſplanted.

But remember to plant them at ſuch a diſtance, that each plant may have full room to grow and ſhew itſelf to advantage.

When it is intended to plant them in clumps, or quarters, let the plants in general be ſet at leaſt five or ſix feet diſtant from one another; and ſuch as are of a humble growth, let them not be planted promiſcuouſly among the tall growing plants, becauſe they would be wholly concealed from ſight. Let therefore the low growing plants be ſet towards the front, or outſide of the clump; and the taller the plants are, ſo much the farther back let them be planted.

Tranſplant fibrous-rooted Flowering Plants.

Roſe campions, ſweet-williams, campanulas, catch-fly, rockets, batchelors buttons, double feverfew, ſcarlet lychnis, lychnidea, and other fibrous-rooted perennial plants, ſhould now be tranſplanted into the borders or places where they are wanted. And as theſe are nearly of the ſame height, they are very proper to be tranſplanted into the middle of the border. All theſe, eſpecially thoſe of the double kinds, make a very agreeable appearance at the flowering ſeaſon.

But you ſhould remember to plant ſome of your double roſe campions, double wall-flowers, double ſtock july-flower, double lychnis, double ſweet-williams, and the like, in pots; for as theſe flowers deſerve particular care, they ſhould be ſheltered in ſevere weather.

This

This is alſo a proper ſeaſon to ſlip and plant out where wanted, polyanthuſes, double daiſies, double camomile, violets, London pride, thrift, hepaticas, gentianella, ſaxifrage, and other low growing fibrous-rooted plants. And, as they are but low, they ſhould not be planted more than fifteen or ſixteen inches from the edge of the border.

Columbines, monkſhood, Canterbury bells, foxgloves, tree primroſe, Greek valerian, ſcabiouſes, and the like plants ſhould now be planted into the middle of the beds or borders; for they grow from two to four feet high.

Carnations and pinks, both ſeedlings and layers, double walls, and double ſtock-july flowers, ſhould now be planted in the beds or borders.

But the Michaelmas daiſies, golden rod, everlaſting ſun-flowers, French honey-ſuckles, and holly-hocks, are much better planted in clumps among flowering ſhrubs, than in beds or borders, unleſs they are planted toward the further ſide; and then they ſhould be ſet fifteen or twenty feet diſtant from one another.

Plant Ever-green Trees and Shrubs.

You may now remove moſt ſorts of ever-green trees and ſhrubs; but the ſooner it is done in the month the better.

The arbutus, or ſtrawberry tree, laurel, Portugal laurel, lauruſtinus, pyracanthas, phillyreas, alaturnus, bays, ever-green oaks, cytiſuſes, hollies and magnolias, may, particularly, be now removed with ſafety. Theſe ſhould all be planted in clumps, and four or five feet every way aſunder; for at that diſtance each plant will have room to ſhoot every way regularly, and form handſome heads. At the ſame time you will have room to hoe, dig, and cleanſe the ground about the ſhrubs, which will be of the greateſt advantage to them.

Tranſplant Pines, Firs, &c.

Pines, firs, cedars, junipers, and cypruſſes, may be ſafely removed any time this month.

Remember to chuſe for them a dry ſoil, and to open for every plant a hole wide enough to receive the roots freely every way; and when the holes are dug a proper depth, to let the ground be well looſened at the bottom.

When the holes are thus prepared, bring the plants, and after ſhortening the ends of their roots and cutting off all that are dead, broken, or damaged, place each plant upright in the hole; break the earth well, and throw it in equally, ſhaking the plant gently, that the earth may fall in cloſely among the roots and fibres. When all the earth is thrown in, tread the top gently round the plant, and give every one of them a little water.

But in planting the more tender ſorts of ever-greens, the plants ſhould, if poſſible, be brought with balls of earth about their roots, and the plants ſet immediately in a hole prepared for their reception, with the balls of earth entire; and as ſoon as the hole is filled up, the ſurface ſhould be trod gently, and each plant have a proper quantity of water.

Trim Ever-greens.

Remember to go often at this ſeaſon round your plantations of ever-greens, reducing to order ſuch as are of an irregular growth. Let all the ſtrong ſtraggling branches be ſhortened; and where the trees interfere with one another, let the branches be ſhortened ſo that every plant may ſtand ſeparate.

Tranſplant Foreſt Trees.

The oak, elm, beech, maple, aſh, lime, and plane trees, may be tranſplanted with ſafety about the middle or latter end of this month. But remember to do it in mild weather, and in a dripping time.

Management of Seedling Flowers.

All your ſeedling flowers in pots or boxes muſt be now removed to a warm ſituation, where the cutting winds have no power, and where they may enjoy the full ſun all the winter. Remember to clear the pots or boxes from weeds.

With regard to your ſeedling flowers in beds, let them be careſully weeded, and then ſome light rich earth ſifted over the ſurface to the thickneſs of half an inch; for this will be of the utmoſt ſervice to the plants, particularly thoſe which were not tranſplanted in the ſummer.

Propagate Roſes and other flowering Shrubs by Suckers.

Roſes, lilacs, and other flowering ſhrubs of that kind are increaſed by ſuckers from the roots; and this is a very proper ſeaſon, if the weather be mild, to tranſplant them. They will make good plants in two years time.

Prune Roſes, Honey-ſuckles, &c.

This is a very proper ſeaſon to prune roſes, honey-ſuckles, and all other ſorts of flowering ſhrubs.

Remember to prune them with a ſharp knife, and to cut off cloſe to the place from whence they proceed, all the ſtrong luxuriant ſhoots of the laſt ſummer's growth: and where any branch advances in a ſtraggling manner from the reſt, let it be ſhortened; obſerving, if poſſible, to cut it cloſe to a young ſhoot.

All ſuckers which riſe from the roots ſhould be taken away, and every ſhrub kept to a ſingle ſtem.

As ſoon as the pruning is finiſhed, let the cuttings and litter be cleared away, and the ground well dug a ſpade deep, cutting off all the ſtraggling roots, and taking up all the ſuckers.

Propagate hardy Trees and Shrubs by Layers.

Moſt of the trees or ſhrubs that ſhed their leaves in winter, may be propagated by layers, and this is a proper ſeaſon for doing it on the hardy kinds. The method is this:

Dig the ground round the tree or ſhrub, bend down the pliable branches, lay them in the earth, and ſecure them with hooked or forked ſticks. When this is done, let all the young ſhoots on each branch be laid down, and the bodies of them covered about three inches deep with earth, leaving the top of each, two, three, or four inches out of the ground.

In this manner they muſt remain till this time twelvemonth, when they will be ſufficiently rooted, and ſhould then be tranſplanted.

Tranſplant Layers.

This is the proper ſeaſon for tranſplanting the layers of ſuch trees and ſhrubs as were layed laſt year. As

ſoon as they are taken up let their roots be pruned, and afterwards planted in rows twelve inches aſunder.

Propagate flowering Shrubs by Cuttings.

Honey-ſuckles, laurels, and Portugal laurels, and many other ſorts of hardy ſhrubs and trees may be raiſed from cuttings, and this is the proper ſeaſon for planting them.

Let the cuttings be choſen from the laſt ſummer's ſhoots, about ten or twelve inches in length, and planted in rows two inches aſunder, and about eight inches apart in the rows.

The cuttings of laurel, and Portugal laurel, ſhould have about two inches of the former year's wood with them.

Plant Box Edgings.

This is the beſt time of the year for planting box-edgings; for the box will now take root freely.

If you intend your edgings ſhould be neat, procure a ſufficient quantity of ſhort buſhy box, which muſt be ſlipped or parted, and the long ſticky roots cut off.

Your box being thus prepared, ſtretch your line along the edge of the bed or border, and let that part be made up all the way pretty firm and full; then with your ſpade cut a trench about ſix or eight inches deep on the ſide of the line next the walk, making the ſide next the line perfectly upright.

In this trench let the box be ſet cloſe againſt the ſide next the line, placing the plants ſo near together, as to form a cloſe compact edging, without being too thick and clumſy; and as you proceed in planting, draw the earth up to the outſides of the plants, which will fix them in the proper poſition. When the row is planted, let the top be cut as neat and even as poſſible with a pair of ſheers.

Plant Thriſt Edgings.

This is alſo a very proper time for planting thriſt; and the ſame method ſhould be followed in planting thriſt as in planting box. The plants, if the edging be intended to be neat, ſhould be ſet ſo cloſe as juſt to touch one another.

Mow Graſs-Walks and Lawns.

If the graſs of your walks and lawns be not well cut at this ſeaſon, they will appear very rough all the winter; let your walks and lawns, therefore, be now mown as cloſe and even as poſſible.

It will alſo be often neceſſary to pole your graſs-walks, in order to ſcatter the worm-caſts, and then to roll them with a wooden roller. For the worm caſts being broken, and ſpread abroad by means of the pole, will readily ſtick to the rollers, and conſequently give the ſurface of the graſs a clean and neat appearance.

NOVEMBER.

Work to be done in the KITCHEN-GARDEN.

Cauliflower-Plants.

REMEMBER to let the air have free acceſs to your cauliflower-plants ſet in frames, every day, by taking the glaſſes entirely off the frame in the mornings, except the weather be extremely wet, when the lights muſt be raiſed a conſiderable height, but not taken away. But let the plants be covered every night.

Whenever you perceive any dead leaves upon your plants, let them be taken away; and be ſure to keep the bed perfectly free from weeds.

The ſame treatment will be neceſſary for your cauliflowers under hand or bell-glaſſes; and it will be of great ſervice to the plants, if a little earth be drawn up round their ſtems.

You may yet plant out cauliflower-plants under hand or bell-glaſſes; but let it be done at the beginning of the month, and the ſooner the better.

Beans.

If you omitted to plant beans laſt month, for an early crop, let it be done at the beginning of this: but if ſome were planted at that time, and theſe are intended to ſucceed them, they ſhould not be ſet till about the latter end of the month.

The mazagan bean is the moſt proper for planting at this ſeaſon, becauſe it comes in the ſooneſt, is a great bearer, and very good for the table.

You muſt remember to plant your beans in a warm border, under a ſouth wall, or other fence, and to follow the inſtructions given in October.

Peas.

About the middle of this month, you ſhould ſow another crop of peas, if a regular ſupply for the table be deſired. But if none were ſown in October, they ſhould be ſown in the beginning of the month.

The early hot-ſpur is the moſt proper for ſowing at this ſeaſon; and it muſt be done in the manner directed laſt month, under a ſouth wall, or other fence.

Sow Carrot-Seed.

Let a little carrot-ſeed be ſown, in a warm border, at the beginning of this month; for there is reaſon to hope it will ſucceed, and produce young carrots for the table early in the ſpring, when they will be very agreeable.

Take up Carrots and Parſneps.

Your carrots, parſneps, and other kitchen-roots, ſhould be taken out of the ground in the beginning of this month, and laid in ſand for winter uſe.

For if theſe roots are ſuffered to continue in the ground, they will canker and rot: beſides, if the froſt ſhould ſet in ſeverely, the ground would be ſo hard, that it would be difficult to take up the roots when wanted.

Let, therefore, the advantage of a dry mild day be taken for digging up the roots, the tops of which muſt then be cut off cloſe, the whole roots well cleaned from

earth, and then carried into ſome convenient dry place to be preſerved for uſe, in the following manner:

Lay on the floor a bed of dry ſand, about two or three inches thick; place the roots upon the ſand cloſe together, obſerving to lay the crowns of the roots outwards.

Cover the roots with ſand two inches thick, then lay more roots upon that, and then more ſand; proceeding in this manner with a layer of ſand, and another of roots, till all are depoſited, covering the upper layer of roots with ſand, and laying ſome dry ſtraw over the whole.

Potatoes.

If any of your potatoes ſtill remain in the ground, let them be taken up as ſoon as poſſible, before the ſevere froſts begin; for theſe roots are very ſoon affected by the froſt, which renders them watery, and unfit for the table.

As ſoon as your potatoes are taken up, let them be laid in a dry room, and covered with dry ſtraw a foot thick, as ſoon as the froſt begins.

It will alſo be neceſſary to look them over from time to time, taking away all ſuch as have any tendency to rottenneſs, for otherwiſe they will ſoon infect the whole heap.

Spinnage.

Remember to keep your beds of ſpinnage perfectly clean from weeds; and wherever you perceive the plants ſtand too thick, let the ſmalleſt be taken up for uſe, ſo that every plant may ſtand ſingly. By this means the ſun and air will have free acceſs to the ſurface of the ground, to warm and dry it, which will cauſe the plants to thrive greatly.

You ſhould alſo remember, in gathering ſpinnage, to cut only the large outſide leaves; by which means the inner ones will grow larger, and be fit to gather in their turn.

Artichokes.

About the middle or latter end of the month, the leaves of your artichokes muſt be cut down cloſe to the ground, and the plants earthed up, to protect them from the ſevere froſts of the winter. There are two methods of earthing, or as the gardeners call it, landing up artichokes. The firſt method is this:

Let trenches, about twenty inches wide, be marked out between all the rows, and the ground dug out a good ſpade deep, laying the earth, as it is dug up, over the rows of the plants, and obſerving to cover the crowns of them ſix or eight inches deep at leaſt.

The ſecond method practiſed by many gardeners is as follows:

The line is to be extended exactly along the middle of the ſpaces, between the rows of the plants, and a mark cut with the ſpade under the line. With theſe lines a kind of beds, four or five feet, are formed, having a row of plants ſtanding along the middle of each bed. The ground is then to be dug regularly bed by bed, digging cloſe about and between all the plants; at the ſame time working, or rearing the earth gradually from the above lines or marks on each ſide the row of plants, into a ridge ſloping equally on each ſide with the row of plants in the middle of the ſaid ridge.

By either of theſe methods the artichokes will be protected from the froſt, unleſs it be remarkably ſevere, when it will be neceſſary to lay over every ridge a covering of ſtraw, or other long litter, which, with the earth thrown up, will be a ſure protection to the plants.

Some gardeners, indeed, content themſelves with covering the plants with long dung; but the plants are not ſo effectually protected by this method, as by either of the former.

You ſhould remember, in dreſſing artichokes, that if any of the ſtrong plants ſhould now ſhew fruit, and you are deſirous of ſaving it, not to cut the leaves, but to tie them up cloſe with a hay-band, and then to lay the earth over the roots as above directed, cloſing it well about the outſides of the leaves. By this method the plant will be preſerved in a growing ſtate, and conſequently bring the fruit to perfection.

Aſparagus.

If your aſparagus beds were not dreſſed laſt month, it muſt be done now, and the ſooner in the month the better.

In order to which, let the ſtems or haulms of the aſparagus be cut cloſe to the ſurface of the beds, and carried away directly.

When this is done, let every weed on the beds be cut up with a ſharp hoe, and drawn off into the alleys.

The beds being thus cleaned, ſtretch your line along the ſide of each bed, and with your ſpade mark out the alleys about eighteen or twenty inches wide; and let the alleys be dug out one ſpade deep, and the earth laid neatly over the beds. Remember, as you go on, to bury the weeds drawn off the beds a proper depth in the alleys, and to make the edge of every bed ſtraight and full.

Sow Raddiſhes.

If a little raddiſh ſeed be ſown at the beginning of the month, in a warm border near a wall, or other fence, there will be great hopes of ſucceſs, provided the weather be not too ſevere. Thoſe that ſurvive the froſt will come early in the ſpring, and are therefore valuable. Remember to ſow the ſeed pretty thick, to do it in a dry day, and to rake it in lightly with an even hand.

Sow ſmall Sallad Herbs.

If a conſtant ſupply of ſmall ſallad herbs, ſuch as muſtard, creſſes, raddiſh, rape, and lettuce, be required for the table, they ſhould be ſown every ten or twelve days.

But the bed ſhould now be made in a warm ſituation, where the earth is rich and light. The bed ſhould be properly adapted to the length of a three-light frame, obſerving to raiſe it a foot or more higher in the back than in the fore part, and to make the ſurface very ſmooth.

When this is done, put on the frame, ſinking the back part of it in the ground, ſo that the ſurface of the bed may be every where within ſix or eight inches of the glaſſes.

The ſeeds muſt be ſown in ſhallow drills, and juſt covered, not more than a quarter of an inch at moſt, with earth.

This being done, put on the glaſſes, and as ſoon as the plants appear, let them have air, by raiſing the lights, or taking them entirely away, as you ſee neceſſary; remembering to cover them cloſe every night.

By

By this method you may raiſe ſmall ſalleting, during the whole winter, without the aſſiſtance of artificial heat, except when the froſt is very ſevere.

Lettuce.

Remember to give your lettuce plants in frames freſh air every day, when the weather is mild and dry, by taking the glaſſes entirely off in the morning: but if the weather be very cold, or likely to be wet, let them be put on again in the evening, otherwiſe the plants may remain uncovered during the night; for the cloſer theſe plants are kept, the weaker they will be when drawn up.

The glaſſes muſt, however, be kept on when the weather is wet; but even then they muſt be raiſed a conſiderable height at the back of the frame; for the plants muſt have a quantity of freſh air.

But in ſevere froſty weather the glaſſes muſt be kept cloſe, and, if neceſſary, other coverings muſt alſo be uſed.

The ſame inſtructions muſt be obſerved with regard to thoſe lettuce plants under hand or bell-glaſſes.

Celery.

Remember to keep your celery now blanching well earthed up, for this will preſerve it from the froſt The earth, after being well broken, ſhould be laid up to the plants within ſix inches of the tops of their leaves.

But be ſure to take care not to lay the earth to the plants too haſtily; becauſe the earth would by that means be forced into their hearts, and cauſe them to rot.

Endive.

Let more of your endive plants be now tied up to whiten; but be ſure to chuſe a dry day for this purpoſe.

When the leaves of the full-grown plants are perfectly dry, let them be gathered up regularly in the hand, and tied together with a ſtring of baſs.

But if the weather be inclinable to be froſty, or even wet, the following method may be practiſed.

Draw up ſome of the beſt and largeſt plants, in a dry mild day, and hang them up by their roots acroſs ſome lines ſtretched in a dry place, for a day or two, in order to drain off the wet from between the leaves.

When the plants are thus dried, let ſome barrows full of dry and light earth be laid in a frame, obſerving to raiſe the earth to the top of the back part of the frame, and let it come ſloping to the front.

As ſoon as this is done, gather up the leaves of the endive evenly in your hand, and let the plants be buried in the above earth, almoſt to the tops of their leaves; and when the weather is very wet or froſty, let the glaſſes be cloſe ſhut, and other coverings uſed when thought neceſſary.

If you have not a frame at liberty, earth may be laid in any dry open ſhed; remembering to raiſe the earth in a high ridge. In this earth, let the plants be placed as above directed, obſerving to cover the plants with long litter, when the froſt is ſevere.

By either of the above methods, endive may be blanched in any of the winter months, and, conſequently, a proper ſupply be procured for the table, provided care be taken to have a ſufficient quantity of plants againſt the dreary ſeaſon.

If you have neither the convenience of ſhed or frame, you may practiſe the following method.

Dig a ſmall ſpot of ground in a border, under a ſouth-wall, or other fence, remembering, as you dig it, to throw up the earth in a high ſharp ridge lengthways the border, making the ſouth-ſide as ſteep as poſſible; and let the endive plants be prepared as above directed.

When the bed is thus prepared, gather up the leaves of every plant cloſe and regular, and put them into the earth on the ſouth-ſide of the ridge almoſt to the tops of their leaves. But remember that the plants are not to be ſet in an upright manner, but placed as it were on their ſides, in a ſloping manner, like the ſurface of the bed: one or two rows may be put in lengthways the ridge.

The plants, by this contrivance, will blanch freely; nor will there be any danger of their rotting, for too much wet cannot lodge on the ſurface of the bed.

But you muſt remember to cover the plants in ſevere froſts, with peas-haulm, fern, or ſome other dry long litter.

The endive plants in the bed muſt alſo be covered in hard froſt; for theſe plants cannot endure ſevere cold.

Cardoons.

As your cardoons advance in height, let them be earthed up: but remember to gather their leaves up very cloſe and even, and to tie them together with a hay-band; and to break the earth well before it be laid up to the plants.

A dry mild day ſhould alſo be choſen for this work; for if the leaves of the plants are not perfectly dry when the operation is performed, they will rot.

Onions.

Remember to pick out all the weeds carefully from the beds of your ſpring onions; for they will otherwiſe ſoon overtop and deſtroy the plants.

Manure and Trench your Garden Ground.

Let the rotten dung from your old hot-beds be now laid on the ſurface of ſuch parts of your kitchen-garden as want manure.

At the ſame time, let all ſuch pieces of ground as are now vacant, be dug, trenched, and ridged up; that every advantage may be reaped from the influence of the ſun, rain, and froſt.

Let the ridges be dug about two or three ſpades broad, laid up rough, and as high and ſharp as they will ſtand. Theſe ridges will be eaſily levelled down in the ſpring, when the ground is wanted for the reception of ſeeds or plants.

The NURSERY.

Management of Seedling Plants.

You muſt remember to ſhelter your ſeedling exotic plants in beds, from the ſharp froſty weather. This may be done by laying fern, peas-haulm, or other

light ſubſtance, about the ſtems, and over the tops of the plants; obſerving to take it away when the froſt breaks.

Or by placing ſome hoops acroſs the bed, and throwing thick mats over the hoops, when the froſt is very ſevere.

With regard to your plants in pots, it will be proper to plunge the pots to their brims in a dry warm ſpot of ground; and, if the froſt be very ſevere, to place hoops over the pots, and cover them with mats.

Management of new-planted Trees and Shrubs.

The greateſt care ſhould be taken to protect the roots of new-planted trees and ſhrubs from froſt; particularly thoſe of the more tender kinds.

In order to this, let mulch or long litter be laid a conſiderable thickneſs over the ſurface of the earth between the plants, for this will prevent the froſt from penetrating to their roots.

At the ſame time, let all your new planted trees which are tall be ſtaked, and the ſtems tied faſt to theſe ſtakes, that violent winds may not blow them to one ſide.

Finiſh Tranſplanting.

All the trees and ſhrubs you intend to tranſplant this year muſt be removed before the middle of the month. Indeed it will not be prudent to defer it ſo long; for if the hard froſts ſhould ſet in before the trees have taken root, they will, in all probability, miſcarry.

Dig and Trench Ground for new Plantations.

Where new plantations are to be made in February or March, the ground ſhould now be well dug and trenched; by which means it will be in fine order to receive the plants in the ſpring.

Manure the Ground.

Let dung be laid on the ſurface of ſuch parts of the nurſery that want manuring; but remember to chuſe dry or froſty weather for this work.

It will alſo be of great benefit to your young trees, if a little dung be now ſpread over the ſurface of the ground where they ſtand; for the rains will waſh the ſalts of the dung, in which its virtues conſiſt, into the ground among the roots.

The FRUIT-GARDEN.

Prune Peach, Apricot, and Nectarine Trees.

Any time this month is a proper ſeaſon for pruning peach, apricot, and nectarine-trees; obſerving the ſame method as mentioned in the preceding month.

The laſt ſummer's ſhoots are to be preſerved in every part, at proper diſtances; for on theſe ſhoots principally all the above trees produce their fruit.

At the ſame time, let the old naked branches, which have no ſhoots upon them, be either entirely cut off, or ſhortened to ſome convenient branch that ſupports ſuch ſhoots; always remembering to cut them off cloſe, and to make the cut very ſmooth.

In a word, let ſome of the old wood, in every part of the tree, be cut away every year in the winter pruning, in order to make room for the laſt ſummer's ſhoots, a ſufficient ſupply of which ſhould be left in every part, at convenient diſtances, for bearing fruit next ſummer; cutting away all that are not wanted for that purpoſe.

At the ſame time, the young ſhoots that are left muſt be ſhortened, more or leſs, in proportion to the vigour of the tree, and the ſtrength of the different ſhoots. For by this means the ſhoots will produce a ſufficient ſupply of new ſhoots next year, for bearing fruit the year enſuing.

It may not be amiſs to repeat the cautions given laſt month with regard to theſe trees, namely, as ſoon as you have pruned one tree, to nail up the branches before you begin another; and to nail the branches and ſhoots ſtraight and cloſe to the wall, at about ſix inches diſtant from one another.

Prune Apple, Plum, and Pear-Trees planted againſt Walls or Eſpaliers.

The above trees may be pruned any time this month; but remember to examine them attentively, and to cut out of every part of the tree all the old and uſeleſs wood.

At the ſame time, wherever a ſupply of young bearing wood is wanting, let a ſufficient number of the beſt ſituated ſhoots of the laſt ſummer's growth be left. But theſe ſhoots muſt not be ſhortened: each muſt be laid in at its full length; for each of theſe ſhoots will, the ſecond or third year, begin to produce thick, ſhort ſhoots, or ſpurs, about an inch long; and upon theſe ſhoots, or natural ſpurs, only, the fruit of theſe trees is produced. Conſequently, if the ſhoots laid in for bearing were to be topped, or ſhortened, they would produce no ſuch ſhoots or ſpurs, and therefore no fruit; but inſtead of theſe ſpurs, or bloſſom-buds, they would ſend out ſtrong, and entirely uſeleſs, ſhoots. By which means the tree would be crowded with needleſs wood, and, at the ſame time, not produce one tenth part of the fruit it would have done, had the branches been laid in at full length.

Hence it plainly appears, that neither the old nor young branches of any of theſe trees are to be ſhortened at this or any future pruning, either in ſummer or winter.

At the ſame time, all the branches ſhould be carefully examined, and where there are any old naked branches, or ſuch as ſupport very little bearing wood, let them be taken away, to make room for training more promiſing branches, and form, in a regular manner, a conſtant ſupply of young wood.

As ſoon as all the old and uſeleſs wood is cut away, let all the remaining uſeful branches be well examined; and wherever you perceive theſe ſtand too cloſe, let ſome of them alſo be taken away; remembering to clear out thoſe which grow in the moſt irregular manner, and ſuch as can beſt be ſpared; but be ſure not to let any two branches grow acroſs one another; nor any remain at leſs than ſix inches from the next.

Remember alſo when you take away any branch, to cut it off quite cloſe; for no ſpurs but thoſe naturally produced muſt be left.

Let all the branches, as ſoon as the pruning is finiſhed, be laid in horizontally, trained ſtraight and cloſe, at regular diſtances, and immediately nailed to the wall, or tied to the eſpalier.

Prune

Prune Cherry Trees.

Your cherry-trees, whether ſtandards, or dwarfs planted againſt walls, ſhould now be pruned.

With regard to the wall cherries, the ſame method before laid down for pruning plums, &c. muſt be obſerved. All ſuch old branches as ſupport but little or no bearing wood, muſt be taken away, in order to make room to train the full bearing branches, together with the laſt ſummer's ſupply of young wood, in a regular manner.

At the ſame time, wherever a ſupply of new wood is wanting, remember to leave, in proper places, a ſufficient number of the laſt year's ſhoots; but all thoſe which are not wanted for the above purpoſes, muſt be now cut off cloſe.

You muſt alſo remember not to ſhorten any of theſe ſhoots or branches: they muſt be lain in at full length; for cherry trees, like thoſe of the apple, pear, and plum, produce their fruit principally upon ſpurs; and the branches, if not ſhortened, will begin to produce theſe ſpurs in the ſecond year.

Be particularly careful in pruning morella cherry-trees, always to leave a ſufficient ſupply in every part of the tree of the laſt ſummer's ſhoots, about five or ſix inches apart; for this ſpecies of cherry-tree produces the greater part of its fruit upon the laſt year's ſhoots.

Prune Vines.

Any time this month will be a proper ſeaſon for pruning your vines, whether planted in vineyards or againſt walls.

In pruning vines remember to cut out all the old uſeleſs wood, in order to make room for the bearing ſhoots or branches; and to leave, in every part, a proper ſupply of the laſt ſummer's ſhoots to bear fruit the next ſeaſon.

For theſe ſhoots will, in the ſpring, produce from every eye, or bud, a young ſhoot, and on theſe young ſhoots the grapes are produced the ſame ſummer, the bearing ſhoots of vines being in general produced from branches one year old.

It is therefore neceſſary to leave at this pruning a ſufficient ſupply of the laſt ſummer's ſhoots in every part of the vine.

But in doing this let the ſtrongeſt and beſt ſituated ſhoots, and ſuch as have the ſtrongeſt joints, be choſen; and let each be ſhortened in proportion to its ſtrength. That is, the ſtrongeſt ſhould be cut off at the fourth or fifth eye, and thoſe that are weaker about the third.

For if the ſhoots are left longer, they will fill the vine during the enſuing ſummer with more ſhoots than you can find room to lay in. At the ſame time the fruit on ſuch ſhoots will be ſmall, ill grown, and ill ripened. But if the ſhoots be ſhortened to the lengths above mentioned, they will each, next ſummer, produce three or four good ſhoots, and every one of theſe plants two or three bunches of fruit, which will grow very large, and ripen kindly.

You muſt remember in ſhortening the ſhoots, to cut them off about an inch above an eye, and to make the cut ſloping; at the ſame time not to leave any branches nearer to each other than ten or twelve inches.

Let care be taken to prune your vines in ſuch a manner, that there may always be a ſucceſſion of young branches near the bottom; becauſe theſe will ſupply the place of old naked wood, which muſt, every year, be cut out as it becomes uſeleſs.

Nor ſhould you ever ſuffer any of the old naked branches to remain, unleſs there be no younger branches or ſhoots properly ſituated to ſupply their place.

As ſoon as the pruning is finiſhed, let the branches be laid in ſtraight and regularly, about ten or twelve inches from one another, and nailed up neatly.

Prune Gooſeberry and Currant-Trees.

This is a proper ſeaſon for pruning gooſeberry and currant-trees, a work which gardeners too often neglect, though the fineneſs of the fruit greatly depends upon it.

Let all the old wood be cut out as it becomes uſeleſs, and young branches left to ſupply its place. At the ſame time the branches ſhould be kept free and clear from one another.

Nor muſt you ſuffer any ſuckers from the roots to ſtand for bearing branches; theſe muſt be entirely cleared away every year.

Prune Raſpberries.

It is not yet too late to prune raſpberries, which muſt be done in the manner directed laſt month. After which the cuttings are to be cleared away, and the ground dug between the plants.

Prune Standard Fruit-Trees.

This is the proper ſeaſon for examining your ſtandard apple or pear-trees, either in the orchard or garden; and wherever you perceive any dead or very old branches let them be cut away, together with any large branches that grow in a rambling manner acroſs the reſt.

At the ſame time, where you obſerve the branches to ſtand too cloſe, ſo as to interfere with one another, let the moſt irregular growers be taken away.

By dreſſing your orchard in this manner, you will have handſome and laſting trees, which will produce large and well taſted fruit.

As ſoon as you have finiſhed pruning, let all the moſs, if any be found on the ſtems or branches, be cleared away.

Tranſplant Peach, Nectarine, and Apricot-Trees.

You may ſtill tranſplant peach, nectarine, and apricot trees, provided it be done when the weather is open.

If you intend to make an intire new plantation of theſe trees, let the method laid down in the Introduction to this Kalendar be followed.

But if only a few trees are wanted in different places, it will be ſufficient to trench the border in the parts the trees are to ſtand, adding a little dung, and a proper quantity of good loam, where it can be procured; if not, freſh earth muſt ſupply its place.

Remember to let the trees ſtand fifteen or ſixteen feet from one another, and the ſtem of each tree to ſtand four inches at leaſt from the wall.

Tranſplant Apple, Pear, Plum, and Cherry-Trees.

Any time this month when the weather is open, will be a proper ſeaſon to tranſplant apple, pear, plum, and cherry-trees, where they are wanting.

Remember

Remember, if these trees are to be planted against walls, to allow them sufficient room, a caution that has been too frequently forgot in plantations; for how often do we see them blended together, before the trees are half grown to their proper size; by which means the bearing wood is obliged to be cut away, and the trees are starved for want of nourishment; for their roots, as well as their branches, will interfere with one another.

Let your trees therefore be set fifteen feet from one another, at least; if sixteen the better. Apples and pears will require eighteen or twenty.

At the same time let the border be trenched up two spades deep, and some very rotten dung laid in; unless the earth of the border be naturally bad, when a quantity of fresh loam should, if possible, be procured, and worked up well with a little rotten dung, and some of the earth of the border. In this compost the trees will thrive well; for fresh loam is of the utmost consequence.

Transplant Standard Fruit-trees.

This is also a proper season for transplanting standard fruit-trees. It may be done any time in the month, provided the weather be mild and open.

Remember not to set these trees nearer to one another than thirty feet, whether they be planted in the garden or orchard. The method necessary to be followed in making these plantations has been already laid down in the Introduction to this Kalendar.

Transplant Mulberry, Medlar, and Quince-trees.

Mulberry, medlar, and quince-trees, may now be safely transplanted, for they will succeed. The very same method is to be followed in planting these, as in planting other fruit-trees.

Plant Raspberries.

You may still make new plantations of raspberries; but the sooner it is done the better.

The plants must be set in an open spot, in rows four feet asunder, allowing three feet between plant and plant in the rows.

Plant Filbert-trees, &c.

This is a proper season for planting filbert and hazle nut-trees, where they are wanted.

They will both thrive in almost any situation, provided the ground be not too wet in winter; they are generally raised by suckers from the roots.

These should be planted in rows ten or twelve feet asunder, and the plants six feet apart in the rows.

General Directions for Planting.

The following instructions should be constantly observed in planting all kinds of fruit-trees.

1. Let a hole be opened for each tree, wide enough to let the roots spread freely and equally every way; and let the ground at the bottom of the hole be well loosened with a spade.

2. Let the roots of the trees be pruned; that is, all the broken and bruised parts be cut off, the stragglers shortened, and the ends in general trimmed. For this will make them produce new fibres more freely.

3. Let no tree be ever planted too deep; that is, never let the upper-part of the root be more than three inches below the common surface of the ground.

4. Let the tree be placed perfectly upright in the hole, and let the earth be well broken, and thrown in equally about all the roots, the tree being at the same time shook gently, that the earth may fall in equally between all the small roots and fibres.

5. Let the surface of the ground, when the hole is filled up, be trodden gently round the tree.

The PLEASURE or FLOWER-GARDEN.

Plant Tulips, Ranunculusses, and Anemonies.

You may still plant the roots of tulips, ranunculusses and anemonies, provided it be done in mild open weather, and before the middle of the month.

With regard to the tulips planted in beds, let them be set in rows nine inches asunder, the same distance being allowed between the roots in each row.

The beds should be of rich light earth, situated in a dry part of the garden, for too much wet would rot the roots.

The ranunculusses and anemonies should also be planted in beds of light earth, laid up rounding, that the water in hasty rains may not continue long enough on the bed to rot the roots.

The beds where these roots are planted should indeed be covered, as they should be protected in winter from severe cold, and in the spring, when they are in bloom, from the rains and sun. The same distance in planting these roots, must be observed as mentioned last month.

But if they are planted in borders, it will be proper to plant them in small clumps or patches, each containing four or five roots, and to allow an interval of nine or ten feet between the patches.

The roots must not be planted more than two or three inches deep; the tulips should be four or five.

Plant Crocusses.

Crocusses, and other small bulbous roots, may also now be planted. But let them be planted in patches, as mentioned last month.

Remember not to put the roots above two or three inches under the surface of the grond.

Plant Narcissus's, Jonquils, &c.

This is also a proper season for planting narcissus's, jonquils, and, indeed, all other bulbous roots that are still above the ground. But remember to do it in mild open weather, and to follow the directions given for that purpose last month.

Set Perennial Plants.

You may still plant double scarlet lychnis, double rose campion, double rocket, catch fly, campanulas, batchelors-buttons, sweet-williams, wall-flowers, stock july-flowers, columbines, Canterbury bells, tree primrose, Greek valerian, perennial sun-flower, golden rod, perennial asters, holly hocks, French honey-suckles, monkshood, pionies, London-pride, gentianella, double daisies, polyanthuses, primroses, and many other sorts.

But remember, in planting the different ſorts, to let all the large or tall growing plants be placed backwards in the border or clump, and to ſet them at a good diſtance from one another.

Remember alſo to intermix the different ſorts in ſuch a manner, that every part may have both an agreeable variety and a continual ſucceſſion of flowers.

Plant Box.

It is not yet too late to plant box edgings to beds or borders, where wanting. At the ſame time all gaps or uneven places may be repaired.

Tranſplant hardy flowering Shrubs.

You may ſtill, when the weather is mild and open, tranſplant roſes, honey-ſuckles, ſyringas, lilacs, laburnums, bladder and ſcorpion ſena, althæa frutex, double flowering cherry, jaſmines, gelder roſe, and many other hardy ſhrubs, for they will yet ſucceed.

Remember to take away the ſuckers, and to plant them in an open ſpot, where they will make pretty plants in two years time, and may then be removed into the clumps or borders.

Tranſplant Foreſt Trees.

Foreſt trees of all kinds may yet be tranſplanted, when the weather is mild and open. Remember to ſtake them properly, in order to ſecure them from the power of the wind, as ſoon as they are planted.

Prune flowering Shrubs.

Let all the long rambling ſhoots of the laſt ſummer's growth be cut away from your flowering ſhrubs, together with all the dead wood; and the irregular branches ſhortened.

Where the branches of any ſhrub ſtand too cloſe, let ſome of the worſt of them be taken away, and the reſt left at regular diſtances.

At the ſame time remember not to let the branches of any two ſhrubs interfere with one another: for every plant appears more agreeable to the eye when it is kept ſingle, than when intermixed with another.

As ſoon as the pruning is finiſhed, let the ground between and round about the plants be dug one ſpade deep, and all the ſuckers ſent up from the roots of the ſhrubs, taken away.

Management of new Planted Trees.

You muſt be very careful, when the froſt ſets in, to protect the roots of your new planted trees, particularly thoſe of the more choice and tender kind, by covering the ſurface of the ground with mulch.

At the ſame time let ſtakes be firmly fixed in the ground near the taller trees and ſhrubs, and their ſtems faſtened ſecurely to the ſtakes. This ſhould indeed be done when the trees are planted; but if not, let it be done now, and the ſooner the better; for as long as the wind has power to rock them at their roots, they can put out no new fibres; or if any are ſhot out during a calm of two or three days, they will be broken, or at leaſt diſturbed, by the firſt high wind. You therefore cannot be too careful in this particular. Let the ſtake be ſtrong enough to ſupport the plant, and let the ſtem of it be tyed to the ſtake in a neat and ſecure manner.

Management of Auriculas, and Carnation Layers in Pots.

Remember to defend your auricula plants and carnation layers planted in ſmall pots, from the froſt and heavy rains.

In order to this, let the pots be plunged up to their rims and cloſe together in a bed covered with a garden frame; and when the weather is unfavourable, let the glaſſes be put on to defend the plants.

If you have not the convenience of a frame, let the pots be plunged in a bed of dry earth, having hoops placed acroſs it; and when the weather is either very cold or wet, let the hoops be covered with mats or canvas.

But remember to take off the coverings, whether glaſſes, mats, &c. in dry open weather, when they ſhould not be covered even at nights.

Management of Seedling Flowers.

If your pots or boxes of ſeedling flowers were not removed into a warm ſituation laſt month, let them be removed at the beginning of this.

The moſt certain method to ſecure the plants from hard froſts, is to plunge the pots or boxes into the earth of a dry warm border; and when the weather proves very ſevere, to cover them with mats or long litter.

Management of Hyacinths, Tulips, &c.

Be very careful to ſhelter the beds where your choiceſt hyacinths, tulips, ranunculuſſes, and anemony roots are planted, in heavy rains, ſharp froſts or ſnow, by drawing the mats or canvas over the hoops placed acroſs the beds. For if either too much rain or ſnow be ſuffered to remain upon the beds, the wet will penetrate to the roots, by which means many of them muſt be deſtroyed, and all of them conſiderably injured.

Management of Graſs Walks and Lawns.

As the worms at this ſeaſon throw their caſts up very faſt and thick, the graſs will become dirty, unleſs you take care to pole and roll it often.

Let therefore the long pliable pole be frequently uſed, in order to break and ſcatter the wormcaſts; and the graſs afterwards well rolled with a wooden roller. By this method the graſs walks will be firm, ſmooth, and entirely clean; for all the wormcaſts will ſtick to the roller.

Remember to chooſe the drieſt days for this work, and let it be conſtantly done once a week during the winter ſeaſon.

This is alſo the ſeaſon for clearing your walks from the leaves of trees, which being all fallen, ſhould be cleared away from every part of the garden.

Management of Gravel-Walks.

Many throw up their gravel-walks in ridges at this ſeaſon, in order, as they pretend, to kill the weeds; but experience has ſufficiently ſhewn that it will not anſwer the intention. It is therefore a much better method to let them continue as they are; for the ridging renders them entirely uſeleſs, and gives a very diſagreeable appearance to the whole garden.

Let them therefore remain in their preſent ſituation, keeping them entirely free from weeds and moſs, which

will

will now ſpread apace, and rolling them once a week, when the weather is dry.

Prepare Compoſt for Flowers.

Your heaps of compoſt ſhould be now turned, if omitted laſt month, remembering to break the clods very well, and to mix all the parts thoroughly together.

Clear the Borders.

Let all your dead annual plants, ſuch as French and Aſiatic marigolds, Javeteras, China aſters, and other plants of that kind, be pulled up by the roots; and all the ſtems or decayed flower ſtalks of perennial plants, be cut down; and the borders cleared from the leaves of trees and all other litter.

When this is done, let the ſurface of the borders be gone over with a Dutch hoe in a dry day, and the ſurface raked ſmooth.

This being done, look round your borders, and wherever you perceive any perennial plants wanting, thruſt a ſtick into the earth as a mark where it ſhould be planted.

DECEMBER.

Work to be done in the KITCHEN-GARDEN.

Plant Aſparagus.

IF early aſparagus be deſired, a hot-bed ſhould now be made for raiſing them.

In order to this, let the dung intended for the bed, be thrown up in a heap ten or twelve days before you uſe it; for in that ſpace of time it will be in proper order.

Remember to make the bed two inches wider on every ſide than the frame; and three feet and a half high.

When the bed has been made two or three days, level the top, and cover it equally ſix or ſeven inches thick with earth, making the ſurface perfectly even; but do not yet put on the frame.

This being done, the aſparagus plants are to be immediately placed on the ſurface, cloſe to each other, in the following manner.

Let a ſmall ridge of earth, about four inches high, be raiſed upon the ſurface, at one end of the bed. This being done, place a row of roots cloſe together againſt the above ridge, and then another row of roots againſt the former; proceeding in this manner till the whole bed is filled with roots, except two or three inches on each ſide of the bed, which muſt be left to ſupport ſome moiſt earth, which it is neceſſary to bank up againſt the outſide roots, on each ſide of the bed.

This being done, let good light earth be thrown equally over the bed, till the crowns of the roots are covered above two inches thick; and two or three pots of water poured on the ſurface to waſh the earth in among the roots; adding, after the watering, a little more earth, that the crowns of the roots may continue covered two inches thick.

In this manner the bed is to remain till the aſparagus begins to appear through the covering of earth; when another parcel of earth, to the depth of three or four inches, is to be laid upon the bed; ſo that the crowns of the roots may now be covered five or ſix inches deep.

The bed being thus prepared, thick bands or ropes of ſtraw muſt be fixed round the bed for the frame to reſt upon. This is done in the following manner:

Let ſome bands of ſtraw, about three or four inches thick, be made, and faſtened down round the upper part of the bed, with ſtakes about two feet long, ſharpened at one end in ſuch a manner that the upper part of the ſtraw may be exactly level with the ſurface of the earth; remembering to thruſt the ſtakes down into the dung of the bed. This being done, let the frame and glaſſes be immediately placed on the band of ſtraw.

If any heavy rains or great ſnows ſhould happen to fall during the time the bed continues without a frame, it muſt be defended with a good thick covering of ſtraw, or mats.

By this method the buds will riſe very thick in about a month or five weeks time, and grow ſurpriſingly faſt.

When you perceive the heat begins to decline, which will happen in about eighteen or twenty days after the bed is made, it muſt be renewed by applying a lining of freſh dung to the ſides. Nor ſhould you forget, when the buds begin to appear, to cover the glaſſes every night with mats or long litter.

Remember to place the crowns of the roots upright when you ſet the plants in the bed, and to gather the roots of each plant cloſe together, ſo that a bed adapted to a three-light frame, may contain at leaſt three or four hundred roots.

The plants for this purpoſe ſhould not be leſs than three, nor more than five years old.

Set Beans.

If you did not plant any beans laſt month, a few ſhould be planted at the beginning of this; but if they are to ſucceed the former plantation, the middle of the month will be ſoon enough.

In order to this, let a piece of ground be prepared in a ſheltered ſituation, and mazagan beans, for theſe will come the earlieſt, planted in rows two feet and a half aſunder, and the beans four inches apart. They ſhould be planted about two inches deep in the ground.

About the laſt week in this month a few Sandwich beans may be planted; they will come at a right time to ſucceed the crop of ſmall early beans, planted at the beginning, or in the middle of the month.

They ſhould be planted about three inches deep, in rows three feet aſunder, and the beans five or ſix inches apart in the rows.

At the ſame time, care ſhould be taken to guard thoſe beans which are up from the froſt, by drawing the earth up to their ſtems as they advance in height; but remember to do

do it in a mild dry day, and when the ſurface of the earth alſo is tolerably dry.

Sow Peas.

Let a ſpot of ground be got ready, when the weather is open, for ſowing another crop of peas, to ſucceed that ſown in the foregoing month.

The ground being prepared, draw ſmall drills about three feet aſunder, and ſcatter the peas, which ſhould be the earlieſt hotſpur, pretty thick in the drills, covering them with earth about an inch and a half deep.

Theſe peas may be ſown any time this month, when the weather is open; but if they are to ſucceed thoſe ſown in November, the middle of the month will be the moſt proper ſeaſon.

Remember, if you have any peas above the ground, to draw ſome earth up to their ſtems, to protect them from wet and froſt; but this muſt be done in a dry mild day, and the earth broken very fine before it is drawn up to the plants.

Sow Carrots.

If young carrots be deſired early in the ſpring, a little ſeed may be ſown any time this month, when the weather is mild and dry. And if the ſeaſon proves any thing favourable after Chriſtmas, a few young carrots may be expected pretty early.

In order to this, let a ſpot of ground, in a warm border, be prepared, the ſeed ſown pretty thick on the ſurface, and immediately raked in equally with an even hand.

Sow Lettuce Seed.

Any time this month, when the weather is mild, a little lettuce ſeed may be ſown on a warm ſouth border; and, if the ſeaſon ſhould prove favourable, it will ſucceed tolerably well, and produce plants, which will be very uſeful in the ſpring.

Sow ſmall Salleting.

The ſeeds of muſtard, creſſes, raddiſh, rape, and lettuce, ſhould be ſown once in ten or fourteen days, if a proper ſupply be wanted.

Theſe ſeeds muſt be ſown in a bed of light earth, covered with a frame; the ſeeds alſo muſt be covered near a quarter of an inch with earth.

The glaſſes muſt likewiſe, in general, be kept on the frames; but the plants muſt have freſh air every day, when the weather is mild, by raiſing the glaſſes on props.

When the weather is very fine, which ſometimes happens this month, the glaſſes may be entirely taken away; but be ſure to keep the bed covered cloſe with the glaſſes every night.

Sow Raddiſh Seed.

A little raddiſh ſeed may be ſown any time this month, when the weather is dry and open. The plants, if they ſucceed, will come early in the ſpring.

In order to this, let a ſmall ſpot of ground, warmly ſituated under a ſouth wall, be prepared, the ſeed ſown on the ſurface, and raked in with an even hand. The beſt ſort for ſowing, at this ſeaſon, is the ſhort-topped raddiſh.

If the froſt ſhould be ſevere, you muſt cover the bed with peas-haulm, fern, or other long litter.

Management of Cauliflower Plants.

The cauliflower-plants under frames muſt now be looked over, and all the decayed leaves, which are very injurious to the plants, picked off, whenever they appear.

Be ſure to take off the lights every mild day, that the plants may enjoy the benefit of the free air; but remember to put the glaſſes on every night.

When the weather is very wet, the glaſſes muſt not be removed, but propped up a conſiderable height at the back of the frame; for theſe plants require a large quantity of freſh air.

In ſevere froſty weather, however, it will be neceſſary not only to keep the plants conſtantly covered with the glaſſes, but alſo to lay a covering of ſtraw, fern, or long litter, over the glaſſes, and round the outſides of the frame.

With regard to the cauliflower plants under hand or bell-glaſſes, the ſame management will be neceſſary for them as for thoſe under frames.

Management of Lettuce Plants.

You muſt remember, every mild and dry day, to uncover your lettuce plants under frames; for a free circulation of freſh air is neceſſary to their growth: nor ſhould you put on the glaſſes at night in very mild weather.

When the weather is very wet, the glaſſes muſt not be removed, but raiſed up a conſiderable height at the back of the frame, by which means a quantity of freſh air will be admitted to the plants.

In froſty weather, the plants muſt be covered cloſe with the glaſſes; and if the froſt be very ſevere, it will be neceſſary to add a covering of mats, ſtraw, fern, or long litter.

Remember to take away all decayed leaves whenever any appear upon the plants, and to keep them entirely free from weeds.

Earth up Celery.

The firſt mild dry day, when the plants are perfectly dry, let your celery be earthed up; but remember to break the earth very ſmall, and to lay it up carefully againſt the plants, ſo as neither to break their leaves, nor bury their hearts.

The plants ſhould, if poſſible, be earthed up within four or five inches of their tops; for this will at once defend them from the froſt, and blanch them a conſiderable length.

It will be proper, when the weather is very ſevere, to cover with peas-haulm, fern, or the like, ſome of your beſt celery plants; for by this means the plants will be protected from the froſt, and the ground from being frozen, ſo that you may take up the plants whenever any of them are wanted for the table.

Earth up Cardoons.

Your cardoons ſhould, when the weather is mild and dry, be earthed up, in order to blanch them, and, at the ſame time, to defend them from the froſt.

In order to this, let the leaves be gathered up regularly, and tied together with hay-bands. When this is done,

done, let the earth be well broken, and laid up round each plant, as near the top as poſſible. In very ſevere weather, ſome dry litter ſhould be laid up round your beſt plants, in order to preſerve them from the froſt.

Earth up Artichokes.

If your artichokes were not earthed up laſt month, let it be done, if poſſible, at the beginning of this; at leaſt ſome dry litter laid over them.

The leaves ſhould all be cut down and cleared away; and then the earth laid over the rows of plants, in the manner mentioned laſt month.

But if the ground be frozen ſo hard, that you cannot dig between the plants, or time will not permit your doing it, be ſure to lay ſome dry long litter over and round the plants, to protect them from the effects of the froſt.

Blanch Endive.

More of your large endive plants may now be tied up, in order to be blanched, provided the weather be mild and dry.

In order to which, the leaves ſhould be gathered up evenly in the hand, and tied together a little above the middle of the plant: but remember to let the plants be quite dry before you tie them up, for otherwiſe they will rot.

In very wet or froſty weather, endive cannot be blanched by this method. Some of the fineſt plants muſt therefore be drawn out of the ground the firſt dry mild day, and hung up two or three days by their roots in ſome ſhed, that the moiſture may drain away from between their leaves. When this is done, they are to be blanched in the manner directed laſt month.

Muſhrooms.

The greateſt care muſt now be taken to keep the froſt and wet from your muſhroom-beds. The beſt method of doing this is by covering them a foot thick, at leaſt, with clean ſtraw.

Remember always to examine the covering after heavy rains or ſnows, and wherever you find it wet to the bottom next the bed, let the wet ſtraw be taken away as ſoon as poſſible, and its place ſupplied with dry.

Trenching and Digging.

Remember to employ every minute that can be ſpared in digging and trenching the vacant ſpots of ground, that they may be ready to receive the intended crops in the ſpring.

Let the ground be dug one or two ſpades deep, according to the nature of the crop you intend; obſerving to lay it up in ridges till the time you want to plant or ſow it; by which means the ground will be greatly mellowed and enriched.

When the froſt will not admit of digging, let dung be carried to the different parts of the garden where manure is wanting.

The NURSERY.

Management of new Planted Trees.

Your new planted trees, eſpecially thoſe of the more tender kind, will ſtill require attention. If therefore you omitted to cover the ſurface of the ground about their roots with mulch in November, let it be done now; and the ſooner it is done the better.

Remember alſo to ſupport the ſtems of all new planted tall trees with ſtakes, if you omitted it laſt month; for while any tree is rocked to and fro by the wind, there is no hopes of its taking root.

Management of Seedling Exotic Trees.

All ſeedling exotic trees will, while they are young, require ſome ſhelter in ſevere weather. Remember, therefore, to protect them in the manner mentioned laſt month; but never let the covering remain a day longer than there is an abſolute neceſſity.

At the ſame time, remember to cover the beds where your ſeeds, berries, acorns, &c. were ſown in October, or the beginning of November, with peas-haulm, fern, or other dry long litter. And be ſure to do this before the froſt has penetrated far into the ground. This caution will be particularly neceſſary with regard to your beds of acorns, which will ſoon ſhoot after being committed to the ground, and conſequently will be ſoon greatly affected by the froſt.

Dig the Ground between the Rows of Trees and Shrubs.

Every opportunity, when the weather is open, ſhould be taken to dig the ground between the rows of trees and ſhrubs; taking care to bury the weeds properly, and not to injure the roots of the plants.

Digging and Trenching.

Let the digging and trenching ſuch pieces of ground as are intended to be planted with ſhrubs in the ſpring, be now forwarded as much as poſſible. The ground ſhould be laid up in ridges; becauſe the froſt will have much greater power to mellow it, when laid up in that form, than when dug in the common manner: at the ſame time, the rain will not lie upon it ſo long as on ground laid perfectly flat.

The FRUIT-GARDEN.

Prune Apricot, Peach, and Nectarine-Trees.

It is not yet too late to prune apricot, peach, and nectarine trees: nor will they be much injured even if the weather ſhould prove froſty. If therefore the weather be not very ſevere, theſe trees may be pruned any time this month. Remember to follow the directions laid down in the two preceding months; and to nail up every tree, as ſoon as it is pruned, in a neat and regular manner.

Prune Apple and Pear Trees.

Any time this month will not be too late to finiſh the pruning of your apple or pear trees againſt walls or eſpaliers: for as theſe trees are very hardy, there is not the leaſt danger of their receiving any injury from pruning.

The ſame method muſt be uſed in pruning as was laid down in November.

Prune Vines.

Your vines alſo, whether planted againſt walls or in vine-

vineyards, may now be pruned, obſerving the directions given laſt month.

Prune Standard Fruit Trees.

Remember to examine your ſtandard fruit trees, whether planted in the garden or orchard, at this ſeaſon; and wherever you perceive any dead or ill-growing branches, let them be taken away.

At the ſame time, where the branches ſtand too cloſe, let them be thinned, obſerving to cut out ſuch as grow the moſt irregular, and alſo thoſe which grow acroſs, or interfere with any of the others.

If you perceive any of the ſmaller branches near the upper part of the tree crowded too cloſe together, let ſome of them be taken away. For theſe trees ſhould be moderately thin of branches, and thoſe kept at regular diſtances. By this means the trees will produce a great quantity of large and handſome fruit.

Prune Gooſeberry and Currant Trees.

Your gooſeberry and currant-trees may ſtill be pruned; obſerving the method laid down the preceding month; namely, to keep the branches thin, and at regular diſtances; to ſuffer no branches to remain that grow acroſs each other, and to take away or ſhorten all ſuch as grow in an irregular manner; to keep the hearts of the trees open, to cut out all dead wood, and very old branches, and to clear away all the ſuckers from the roots.

Prune Raſpberries.

If any of your raſpberry-beds ſtill remain unpruned, let it be done now; obſerving the directions given for that purpoſe in October and November.

Plant Raſpberries.

It is not yet too late to plant raſpberries, provided the weather be open. The manner of preparing the plants, and of ſetting them, has been already deſcribed in the two foregoing months.

Plant Gooſeberry and Currant-Trees.

You may ſtill plant gooſeberries and currants for raiſing a ſupply of young trees. The beſt manner of doing this has been already mentioned in October and November.

Tranſplant Gooſeberry and Currant Trees.

Gooſeberry and currant-trees may be tranſplanted any time this month into places where they are wanted, provided the weather be open.

Let theſe ſhrubs, if planted round the quarters of the garden, be ſet ſeven or eight feet diſtant from one another.

Tranſplant Fruit-Trees.

You may ſtill tranſplant moſt kinds of fruit-trees, provided the weather be open; for it muſt not on any account be done when the froſt is ſevere.

Management of new planted Fruit-Trees.

Remember to ſecure the roots of your new planted fruit-trees from froſt, by placing mulch, or ſome kind of long litter upon the ſurface of the ground about the trees, laying it as far every way as you think the roots extend.

At the ſame time, let all your new planted ſtandard fruit-trees be ſupported with ſtakes, if not already done; obſerving to put a piece of hay-band round that part of the tree where it is to be faſtened to the ſtake; for this will prevent the bark of the tree from being rubbed off, when rocked by the winds againſt the ſtake.

Management of Fruit-Tree Borders.

This is a very proper ſeaſon for manuring, or adding freſh earth to fruit-tree borders, where either or both are wanting.

Let therefore a quantity of freſh loamy earth be procured, and mixed thoroughly with ſome of the beſt rotten dung. Let this compoſt be laid upon the ground, dug in, and well worked up with the earth of the border. This will encourage the growth of the trees ſurprizingly, particularly ſuch as are in a declining ſtate, ſo that they will produce large, fair, and well-taſted fruit. But the ſooner in the month the borders have this dreſſing, the better.

If you intend to make new borders for fruit-trees, let the ground be dug when the weather is open; obſerving the directions given in the Introduction to this Kalendar.

The PLEASURE or FLOWER-GARDEN.

Carnation Layers.

Your carnation layers that are in pots, ſhould be covered in hard rains, ſnow, and froſts; but remember, when the weather is open, and not very wet, to let the plants have conſtantly the benefit of the free air.

Auricula Plants.

Be very careful to protect your auricula plants from wet, great ſnows, and hard froſts. If they are placed in frames, let the glaſſes be kept conſtantly over them in bad weather; if in a bed under hoops, let mats or canvas be drawn over them.

But whenever the weather is mild and dry, let the plants be conſtantly uncovered; for a free circulation of air is abſolutely neceſſary.

Protect your Beds of Hyacinths, Tulips, Anemonies, and Ranunculuſſes.

Remember to protect your beds containing your choiceſt hyacinths, tulips, anemonies, and ranunculuſſes; eſpecially thoſe of the two former, when the weather is very ſevere.

In order to this, ſome peas-haulm, fern, or other dry long litter ſhould be provided; and when the froſt is likely to ſet in hard, let a warm covering of it be laid over the ſurface of the beds; but remember to let it be removed when the froſt is not ſevere.

As ſoon as the plants appear above ground, the beds ſhould be arched over with hoops, and a quantity of large thick mats provided, in order to be in readineſs to be thrown over them in hard weather.

Management of Seedling Plants.

Your ſeedling flower-plants will alſo require ſome attention, in order to protect them from injuries during this inclement ſeaſon.

With

With regard to thoſe ſown in pots or boxes, let them be plunged to their rims or tops in a warm border; and long litter laid on the ſurface, when the froſt is ſevere.

Management of new planted Shrubs.

You muſt remember to protect the roots of your new planted trees and ſhrubs, particularly thoſe of the more tender kind, when the froſts are ſevere.

In order to this, a coat of mulch or long litter of a conſiderable thickneſs, muſt be laid on the ſurface of the ground about each plant.

The ground alſo ſhould be dug between all kinds of flowering-ſhrubs, when the weather is open.

Management of hardy Flowering Shrubs in Pots.

Your hardy flowering ſhrubs in pots, ſuch as ſweet-williams, double ſcarlet lychnis, double roſe campion, and other perennial fibrous-rooted plants, will now require attention, to protect them from the ſeverity of the weather.

In order to this, let the pots be plunged to their rims in the earth of a dry warm border, at the beginning of this month. This will prevent the froſt from penetrating to the roots through the ſides of the pot; and with regard to their tops, they muſt be covered in very ſevere weather with dry long litter; but let this covering be taken away as ſoon as ever the weather is any thing mild.

If you have any frames to ſpare, the pots containing any of the above fibrous-rooted plants may be plunged into the earth in the frames, and covered occaſionally with the glaſſes.

Prune Flowering Shrubs.

Examine your flowering ſhrubs, and prune all ſuch as want that operation; but let it be done with a knife, not with the garden ſheers.

Remember, in doing this, to let all the long vigorous ſhoots produced laſt ſummer be taken off quite cloſe, together with all ſtraggling branches; and when the branches are crowded, let ſome of them be cut out in a regular manner.

Let every ſhrub be trained and pruned in ſuch a manner, that it may ſtand entirely clear of all the reſt: the branches of different ſhrubs ſhould never be ſuffered to interfere with one another; for their beauty will be conſiderably impaired by being blended together.

As ſoon as the ſhrubs are all pruned, let the ground be dug between them; remembering to take away all the ſuckers, and to ſhorten all the ſtraggling roots as you proceed.

Prune Foreſt-Trees.

This is a very proper ſeaſon for pruning all ſorts of foreſt trees; for it may be performed in froſty weather, when very little other buſineſs can be done.

Plant Quickſets, and other Fences.

Quickſets, and other ſpecies of thorn, may now be planted for rearing fences. And where the hedges are thin or naked at the bottom, they ſhould now be laid down in ſuch a manner as to render them thick in that part.

Propagate Shrubs by Suckers from the Roots.

You may now propagate roſes, lilacs, and ſeveral other ſhrubs of that kind by ſuckers.

In order to which, let the ſuckers be taken up with care from the old plants in open weather, and planted out immediately in rows fifteen inches aſunder; ſome of them will make good plants in two years time.

Tranſplant Foreſt-Trees, and hardy Flowering Shrubs.

When the weather is open, you may ſtill tranſplant foreſt-trees, and the more hardy flowering ſhrubs.

But remember to cover the ground about them with mulch, as ſoon as ever any of them are planted, to keep out the froſt, if any ſhould happen.

Prepare Compoſt.

Let all your heaps of compoſt be now broken up, and the ſeveral parts mixed very well together.

Prepare Ground for Planting.

When the weather will permit, let the ground, either in the borders or any other part of the garden, where trees or ſhrubs are intended to be planted, be now well dug.

Roll Graſs and Gravel Walks.

Remember to let your graſs walks and lawns be poled and rolled once a week at leaſt, in mild weather.

Your gravel walks alſo muſt be kept very clean, and rolled now and then when the weather is mild and dry.
